

Question 1 of 193

□ □

A 60-year-old man presents to the emergency department with crushing central chest pain. The pain came on suddenly approximately one hour ago. A 12-lead ECG reveals >2mm of ST elevation in all anterior and lateral leads. The nearest centre offering primary angioplasty is 140 minutes away. There is no contraindication to thrombolysis.

In addition to standard acute coronary syndrome treatment (analgesia, aspirin, a heparin and a P2Y12 inhibitor), what is the best management for this patient?

	Immediate transfer for acute angioplasty
	Non-urgent angioplasty
	Thrombolysis
	Thrombolysis and immediate transfer for acute angioplasty
	Thrombolysis and non-urgent angioplasty

Dashboard

Overall score: **0%**

Question 2 of 193

□ □

A 28 year-old man with a background of asthma presents to the emergency department with palpitations.

He reports a 2 day history of coryzal symptoms and wheeze. He has been using his salbutamol inhaler several times per day due to these symptoms.

On examination the patient appears alert and comfortable but complains of a fluttering sensation in his chest. The pulse rate is 180bpm and the blood pressure is 135/90mmHg. Oxygen saturations are 96% on room air.

There is equal bilateral air entry with mild polyphonic wheeze throughout on chest auscultation.

A 12-lead ECG reveals a narrow-complex regular tachycardia at 180bpm with pseudo r' waves after each QRS complex in lead V1.

What is the most appropriate initial management?

	Adenosine 6mg IV
	Metoprolol 5mg IV
	Synchronised DC shock
	Vagal manoeuvres
	Amiodarone 300mg IV

Dashboard

□ Question 3 of 193

□ □

You review a patient in cardiology outpatient clinic. He has a left ventricular ejection fraction of 15% on maximal medical therapy. On reviewing his ECG you note a QRS duration of 135ms without evidence of left bundle branch block. Upon taking a history you note the patient is breathless at rest and struggles to walk around his bungalow.

Which implantable device would be appropriate to consider?

	Cardiac resynchronisation therapy without defibrillator
	Cardiac resynchronisation therapy with defibrillator
	VVI pacemaker
	No implantable device recommended
	Implantable cardioverter defibrillator alone

Dashboard

Question 4 of 193

A 59 year-old man with history of ischaemic heart disease and type 2 diabetes mellitus is eight hours post right curative hemicolectomy for bowel malignancy. In the surgical high-dependency unit he is noted to be tachycardic on the monitor

On examination the patient appears comfortable. The pulse rate is 200bpm and the blood pressure is 148/79mmHg. Oxygen saturations are 98% on 2L/min nasal oxygen. Capillary refill is 2 seconds. The chest is clear to auscultation.

A 12-lead ECG reveals a regular broad complex tachycardia with a monomorphic waveform at a rate of 200bpm.

Post-operative blood tests reveal:

Hb	131 g/l
Platelets	563 * 10 ⁹ /l
WBC	13.4 * 10 ⁹ /l
Na ⁺	141 mmol/l
K ⁺	4.1 mmol/l
Mg ⁺⁺	0.87 mmol/l
Urea	4.2 mmol/l
Creatinine	121 µmol/l
Bilirubin	23 µmol/l
ALP	109 u/l
ALT	34 u/l
Albumin	33 g/l

What is the most appropriate initial management?

	Magnesium sulphate 2g IV
	Amiodarone 300mg IV
	Synchronised DC shock
	Metoprolol 5mg IV
	Adenosine 6mg IV

□ Question 5 of 193

□ □

A 68-year-old male presented 7 days ago with an STEMI. An angiogram reveals significant stenosis in his mid-left anterior descending artery and a drug eluting stent was inserted. Today, he complains of increasing shortness of breath compared to before his admission and is associated with worse lower limb swelling than before. His latest transthoracic echocardiogram reveals an ejection fraction of 33% but his chest x-ray reveals minimal alveolar shadowing only. His medications include:

Ramipril 10mg OD
Bisoprolol 5mg OD
Aspirin 75mg OD
Clopidogrel 75mg OD
Furosemide 80mg OD

How can his heart failure management be optimised?

	Start spironolactone
	Increase furosemide to 80mg BD
	Start eplerenone
	Start candesartan
	Increase bisoprolol to 10mg

Dashboard

Overall score: 0%

□ Question 6 of 193

□ □

A 19-year-old female presents to the medical outpatient with a history of palpitations. She suffers from bouts of anxiety and dizziness associated with these palpitations and has had one episode of syncope. She has had bouts of atrial fibrillation in the past, although documentary evidence is not available.

On examination, her blood pressure is 125/85 mmHg and her pulse is 140 bpm.

Her ECG reveals a broad complex regular tachycardia with a short PR interval and a slurred upstroke of the QRS complex. There is additionally a tall R wave in V1.

Which of the following would be the most appropriate initial step in medical management?

	IV adenosine
	IV verapamil
	IV digoxin
	IV propranolol
	IV procainamide

□ Question 7 of 193

□ □

A 65-year-old man is reviewed in the Emergency Department. Twelve months ago he had a prosthetic aortic valve replacement for progressive aortic stenosis. Since the operation he has been well but over the past two weeks he has been complaining of lethargy, fever and anorexia. Blood tests show a CRP of 215 mg/l. The chest x-ray and urine dip are unremarkable.

Given the suspicion of infective endocarditis an transoesophageal echocardiogram is performed which demonstrates a large vegetative lesion around the prosthetic aortic valve.

What is the most appropriate antibiotic treatment whilst awaiting blood cultures?

	IV amoxicillin
	IV teicoplanin + vancomycin
	IV flucloxacillin + low-dose gentamicin
	IV vancomycin + rifampicin + low-dose gentamicin
	IV teicoplanin + rifampicin

□ Question 10 of 193

□ □

A 77 year old woman is brought to the Emergency Department by blue light ambulance in acute respiratory distress. She has a background history of congestive cardiac failure (NYHA II) due to hypertension and a previous anterior myocardial infarction which was treated medically. She is also a type 2 diabetic and has chronic kidney disease stage 2. She takes aspirin 75mg od, simvastatin 40mg od, ramipril 5mg od, bisoprolol 5mg od, furosemide 40mg bd and vildagliptin 5mg od.

On assessment her airway is patent. Respiratory rate is 32 per minute. Fingertip oxygen saturations are 90% on 15L/min oxygen. There are bilaterally crackles in the chest to above the midzones. Heart rate is 112bpm. Blood pressure is 125/75mmHg. ECG shows sinus tachycardia with no acute ischaemic change. There is peripheral oedema to the mid thigh and the JVP is elevated 6cm.

Which medical therapy is most appropriate immediately?

	3mg bumetanide orally
	80mg furosemide intravenously
	300mg aspirin, 300mg clopidogrel and 2.5mg subcutaneous fondaparinux
	50mg glycerol trinitrate infusion, commencing at 1mg/hr
	5mg metoprolol intravenously

Dashboard

□ Question 15 of 193

An 84-year-old female presents with a three-day history of constant chest discomfort associated with productive green sputum. On admission to the emergency department, a temperature of 38.2 degrees is recorded and she reports a recent history of 'shivering and shaking' over the past 24 hours. She reports no nausea or vomiting and was last well 72 hours ago, when she was living alone with BD carers. She has a known history of bronchiectasis, angina, hypertension, type 2 diabetes mellitus and hypertrophic obstructive cardiomyopathy.

On examination, you note bibasal coarse inspiratory crackles and an ejection systolic murmur. She has noted no deterioration in her exercise tolerance of 150 yards on flat ground. Her blood pressure is 140/85 mmHg heart rate 90/min and regular, Sats 94% on air, respiratory rate 26/min. Her ECG demonstrates ST depression and T wave inversion in V4 to V6, S wave in V1 and R wave in V5 add to 55 mm. You have no previous ECGs to compare this to.

Her blood tests are as follows:

Hb	137 g/l
Platelets	402 * 10 ⁹ /l
WBC	18.3 * 10 ⁹ /l
Neutrophils	16.3 * 10 ⁹ /l

Na ⁺	144 mmol/l
K ⁺	4.3 mmol/l
Urea	6.2 mmol/l
Creatinine	90 µmol/l
CRP	145 mg/l
Troponin < 0.03 (normal < 0.03)	

Her chest radiograph demonstrates left basal shadowing on a background of bibasal tramlining and fibrotic changes. Previous sputum cultures demonstrate pseudomonas colonisation. New sputum and blood cultures have been taken.

What is the most appropriate treatment?

	Intravenous tazocin
	Intravenous tazocin and acute coronary syndrome treatment
	Acute coronary syndrome treatment only
	Oral amoxicillin only
	Oral amoxicillin and acute coronary syndrome treatment

□ Question 17 of 193

A 72-year-old female presents with a 6-month history of gradual onset, progressive exertional dyspnoea associated bilateral increased lower limb pitting oedema. She has no previous cardiac history and prior to 6 months ago, had no limitations to exercise tolerance. Her past medical history includes B cell lymphoma diagnosed four years ago and in remission one course of chemotherapy. **On examination**, the jugular venous pulse is raised at 6cm above the angle of Louis. A soft systolic murmur and bibasal inspiratory crackles can be heard on auscultation. Abdominal examination demonstrates a pulsatile 3cm liver edge. Her blood pressure is 125/77 mmHg, heart rate 68/min and sinus, saturations 92% on 2l, respiratory rate 22/min. **ECG reveals** sinus rhythm of low voltage. **Chest radiography demonstrates** bibasal alveolar shadowing with prominent upper lobe vasculature.

Urine dip is as follows: blood -ve, leucocytes -ve, nitrates -ve protein 3+ pH 5.5.

Blood tests are as follows:

Hb	111 g/l
Platelets	$275 \times 10^9/l$
WBC	$8.3 \times 10^9/l$

Na ⁺	139 mmol/l
K ⁺	4.9 mmol/l
Urea	7.4 mmol/l
Creatinine	140 μ mol/l
CRP	3 mg/l
Trop	<0.03 (normal range < 0.03)

Bilirubin	6 μ mol/l
ALP	32 u/l
ALT	260 u/l

A transthoracic echocardiogram is performed, reported as significant increase in echogenicity, symmetrical left ventricular wall thickening, impaired bilateral diastolic ventricular dysfunction, bilaterally enlarged atria, pulmonary artery systolic pressure 45 mmHg, a 5mm pericardial effusion

What is the most likely underlying diagnosis for this patient?

	Amyloid cardiomyopathy
	Non-ST elevation myocardial infarction (NSTEMI)
	Idiopathic dilated cardiomyopathy
	Chemotherapy induced cardiomyopathy
	Viral pericarditis leading to tamponade

□ Question 18 of 193

□ □

A 65-year-old woman presents to the emergency department with a painful leg. She had noticed that her calf started to become tender when she was getting dressed in the morning and found it to be swollen. She was concerned and called her GP surgery who gave her an emergency appointment. She was seen by her GP earlier in the day who suspected a deep vein thrombosis and advise her to attend her local emergency department.

She has a past medical history of breast cancer which was operated on three months ago with a wide local excision, and she has been told that the operation was successful in removing the cancer. Her observations are stable. On examination, she has a swollen left calf which is mildly tender without erythema. A D-dimer sent by the emergency department team was positive but all other blood tests are normal. She undergoes a doppler ultrasound scan which shows no thrombus. How should she be further managed?

	Start warfarin
	Repeat ultrasound scan within 6-8 days
	CT pulmonary angiogram
	Start treatment dose low-molecular weight heparin
	Repeat D-dimer

□ Question 19 of 193

You are called to see a 68-year-old man on the ward who has ongoing pyrexia for the past week. He was originally admitted after feeling unwell with fevers and rigors, and was treated for a urinary tract infection as his urine dipstick was positive for small amounts of leucocytes and moderate amounts of blood. He was started on co-amoxiclav 1.2g three times a day, and intravenous Gentamicin once daily was added 2 days ago but continues to develop daily fevers and lethargy. His past medical history includes a prosthetic mitral valve, atrial fibrillation, and type 2 diabetes mellitus.

On examination, his temperature is 38.5°C, heart rate of 90bpm, blood pressure 132/76mmHg, respiratory rate of 18 breaths per minute, and oxygen saturations of 99% on air. On close examination, he has splinter haemorrhages in four fingers across both hands, and on cardiovascular examination there is an audible pan systolic murmur not previously documented in the admission notes.

His latest blood results show

Na+	143 mmol/l
K+	4.8 mmol/l
Urea	7.2 mmol/l
Creatinine	88 µmol/l
Serum bilirubin	16 µmol/l
Serum alkaline phosphatase	115 IU/l
Serum aspartate aminotransferase	18 IU/l
C Reactive protein	76 mg/l
Haemoglobin	136 g/l
White cell count	11.6 x 10 ⁹ /L
INR	1.1

Three blood cultures taken one day apart each	No growth at 5, 4, and 3 days.
---	--------------------------------

Mid-Stream Urine culture	Mixed growth
WCC	10/mm ³

What would be the most effective strategy to culture the causative organism?

	Take two sets of optimally filled blood cultures at different sites while he is febrile now
	Take three sets of optimally filled blood cultures within one hour before changing antibiotics
	Take three sets of optimally filled blood cultures within twelve hours before changing antibiotics
	Stop antibiotics for one week, then take three sets of optimally filled blood cultures within one hour
	Stop antibiotics for one week, then take three sets of optimally filled blood cultures at least six hours apart each

Question 20 of 193

A 38 year old female of Asian descent, with no significant past medical history, presents after a syncopal event while pruning hedges. She has had a several month history of fevers, arthralgias and for the past few weeks has had multiple episode of vertigo and one syncopal event. She denies headaches or visual complaints. Her examination reveals a diminished radial pulse in the left arm and a systolic blood pressure difference in the upper extremities of 14 mmHg. A bruit is auscultated along the left upper extremity. Dopplers of the upper extremities indicate a stenotic area along the subclavian that is later confirmed by Magnetic Resonance Angiography (MRA). She is diagnosed with subclavian steal syndrome. Laboratory tests reveal a normocytic normochromic anemia, elevated CRP and ESR, negative ANA and ANCA, and all other laboratory tests are with in normal range. Of the following, What is the most likely diagnosis?

	Fibromuscular dysplasia
	Ehlers-Danlos syndrome
	Takayasu arteritis
	Giant cell arteritis
	Wegener's granulomatosis

□ Question 21 of 193

A 75-year old gentleman with a background of type II diabetes mellitus, ischaemic heart disease (IHD) and New York Heart Association (NYHA) III heart failure presents to your clinic with continuing fatigue and shortness of breath on minimal exertion. He currently takes Aspirin 75mg, Bisoprolol 10mg, Ramipril 5mg, Furosemide 40mg twice daily and Spironolactone 25mg. His electrocardiograph demonstrates left bundle branch block (old) and his ejection fraction is 32% measured by echocardiography at the clinic today. His chest x-ray shows an enlarged cardio-thoracic ratio but no obvious pulmonary oedema. Blood tests taken with his general practitioner this week are as follows:

Haemoglobin	110g/dl
White cell count	11.0×10^9
Neutrophils	7.2×10^9
Platelets	240×10^9
Na ⁺	137 mmol/l
K ⁺	4.2 mmol/l
Urea	9 mmol/l
Creatinine	125 μ mol/l

What evidence-based treatment, if any, is available to treat this gentleman's cardiac failure?

	Increase dose of Spironolactone to 50mg once daily
	Increase dose of Furosemide to 80mg twice daily
	Cardiac-resynchronisation therapy
	Angiography +/- coronary stenting
	He is already on maximal treatment

Dashboard

□ Question 22 of 193

□ □

A 14-year-old female presented to her GP having collapsed at school. Her friends stated that whilst she was playing hockey she inexplicably collapsed and had lost consciousness for a few seconds. This was her first episode of collapse. No seizure activity was observed, and she made a full and spontaneous recovery a few moments later. She denied the presence of prodromal symptoms, and other than occasional palpitations upon exertion she was otherwise well. She had a cochlear implant inserted in early childhood for congenital hearing impairment but otherwise had no past medical history of note, and was not taking any medications. There was no family history of note.

Examination revealed the presence of a healthy athletic 14-year-old female. Her heart rate was 58bpm and regular, and her blood pressure 108/78 mmHg. Cardiovascular examination revealed a JVP of 3cm and was otherwise unremarkable with normal heart sounds. Gastrointestinal examination and neurological examinations were likewise unremarkable.

Initial investigations revealed the following results:

ECG: 57bpm normal, sinus rhythm QRS 112 ms, PR 122ms, QTc 502ms, normal ST and T wave morphology.

What is the most likely diagnosis?

	Brugada syndrome
	Romano Ward syndrome
	Wolff Parkinson White syndrome
	Jervell & Lange-Nielsen syndrome
	Hypertrophic obstructive cardiomyopathy

□ Question 23 of 193

□ □

A 32-year-old male illicit drug user is caught attempting to sell cocaine on the street by the police. On seeing the officers approach him, he swallows a plastic bag containing around 1.5g of cocaine in an attempt to destroy the evidence. The police officers bring the gentleman into the emergency department. He is asymptomatic and complains of no chest pain. His ECG is unremarkable and his admission blood tests demonstrate no abnormalities, including a negative troponin. What should you do next?

	Treat presumptively as acute coronary syndrome
	Discharge the patient to police custody
	Await 12 hour troponin and if negative, discharge to police custody
	Repeat ECG and if no dynamic changes, discharge to police custody
	Monitor the patient until the ingested cocaine is excreted

Question 25 of 193

□ □

A 40-year-old male who is otherwise fit and well presents to clinic with dyspnoea on exertion. This has progressed over the last year to the point where he can only walk 0.5 miles before stopping. He denies having a cough. He has no chest pain. He has smoked 15 cigarettes per day for 25 years. He reports that his father had a myocardial infarction (MI) aged 54 years, but otherwise reports no cardiac-related family history. His body mass index (BMI) is 24 kg/m², heart rate 80/min, blood pressure 130/77mmHg, respiratory rate 18/min and he is saturating at 97% on air. Chest auscultation reveals occasional expiratory wheeze and he has no pedal oedema. Auscultation of the heart reveals a fixed split S2. His jugular venous pressure is not elevated.

Chest X-ray: dilated pulmonary vessels.

ECG: sinus rhythm, 78/min, right bundle branch block (RBBB)

What is the likely cause of his exertional dyspnoea?

	Atrial septal defect
	Ischaemic heart disease
	Bronchial malignancy
	Chronic obstructive pulmonary disease
	Chronic pulmonary embolism

Dashboard

Question 30 of 193

A 55-year-old man presents to the emergency department with shortness of breath.

He reports several months of worsening diarrhoea and is now passing over 10 watery motions per day.

On examination he is dyspnoeic at rest. The blood pressure is 104 / 77mmHg and the pulse rate is 90bpm and regular. Oxygen saturations are 93% on room air. Chest auscultation reveals widespread mild polyphonic wheeze and bibasal crackles. Jugular venous pressure is elevated and C-V waves are present. There is a pansystolic murmur at the left lower sternal border louder in inspiration. There is a palpable liver edge 2cm below the costal margin.

Which investigation is most likely to confirm the diagnosis?

	Growth hormone day curve
	24 hour urine 5-HIAA
	Faecal calprotectin
	24 hour urine VMA
	Stool sample for ova, cysts and parasites

Question 31 of 193

A 23 year old with known ulcerative colitis presents for the fourth time in 6 months with a severe flare. On examination, he has a distended and generally tender abdomen. He was treated with intravenous hydrocortisone, standard 0.9% saline intravenous fluids and thromboprophylaxis. Although AXR demonstrated dilated large bowel loops, no operation was deemed necessary after surgical. The same treatment continued for 3 days. On day 3 of his admission, he reports chest pain with palpitations. A 12 lead ECG was taken:

© Image used on license from Dr Smith, University of Minnesota

What is the underlying diagnosis?

	Hyperkalaemia
	Hypokalaemia
	Hypocalcaemia
	Intravascular depletion → sinus tachycardia
	Atrial fibrillation

Question 33 of 193

A 67-year-old man with a history of heart failure treated with bisoprolol, ramipril, furosemide and spironolactone comes to the clinic for review. His heart failure symptoms are stable, but his main complaint is of painful gynaecomastia that has become more prominent over the past 6 months since he had a medication change. On examination his blood pressure is 125/80 mmHg, his pulse is 65 beats per minute and regular. There are only minor basal crackles at both lung bases on auscultation, and minor pitting oedema of both ankles. Routine blood testing is unremarkable including creatinine.

Which of the following is the most appropriate way to manage his gynaecomastia?

	Change furosemide to bendroflumethiazide
	Change spironolactone to eplerenone
	Stop bisoprolol
	Stop ramipril
	Stop spironolactone

□ □

An 86-year-old female presents to the diabetic ulcer clinic for regular foot care when regular observations note her heart rate to be 42 beats per minute. Her blood pressure is 142/55 mmHg and she reports no recent episodes of syncope. A 12 lead ECG demonstrates Mobitz type 1 rhythm at 42 beats/ minute. A 24 hours tape performed as an outpatient demonstrates bradycardia with up to 2.7 second pauses. Her past medical history includes type 2 diabetes mellitus, hypertension and angina. Her medications include ramipril, furosemide, verapamil, metformin and GTN on an as-required basis. During this second encounter, her heart rate is 41 beats/min and her blood pressure is 115/ 57 mmHg. She informs you that she is guided by you in terms of the most appropriate treatment. What do you advise?

	Temporary pacing wire
	Permanent pacemaker insertion
	Stop verapamil
	Regular digoxin
	Stop furosemide

□ Question 36 of 193

An 80-year-old lady is brought in by ambulance having been found unresponsive by her granddaughter.

She has a history of vascular dementia, hypertension, atrial fibrillation and mild congestive cardiac failure. She lives alone and is visited by her granddaughter, who is her main carer, once per day. Her granddaughter states she has been more confused recently, finding it hard to know the time of day, or whether she had had meals or medications, but has been otherwise well.

She takes aspirin 75mg once daily, amlodipine 5mg once daily, bisoprolol 5mg once daily, ramipril 2.5mg once daily, and simvastatin 40mg at night.

On examination in the Emergency Department she has Glasgow coma scale of 10. Her heart rate is 30/min and her blood pressure is 68/36 mmHg. Her saturations are 95% on 60% oxygen with a respiratory rate of 30 breaths per minute.

She has a regular heart rhythm and normal first and second heart sounds with an S3 gallop. Her jugular venous pressure is raised at 6 cm and she has pitting oedema to the knees. Her capillary refill is 4 seconds and she is peripherally cool. She has fine bibasal crepitations in both lungs. Her abdomen is soft and non-tender. Her temperature is 36.1°C.

Her ECG shows complete heart block with a ventricular rate of 30/min. Her QRS complexes are broad with a right bundle branch block pattern. There are signs of left ventricular hypertrophy but no T wave or ST segment abnormalities.

She is given 3mg of intravenously in atropine 500 mg boluses but heart rate remains 30/min with a blood pressure of 67/40 mmHg.

Which further medication is most likely to result in a sustained improvement in her heart rate?

	Aminophylline
	Dopamine
	Glucagon
	Isoprenaline

□ Question 37 of 193

A 73-year-old gentleman was referred to the cardiology clinic with deteriorating shortness of breath. He was diagnosed by his GP with heart failure following a direct access echocardiogram 6 years ago. Since then he has gradually deteriorated, to the extent that he is now short of breath with minimal activities of daily living. He slept on 4 pillows at night to alleviate shortness of breath symptom which would occur if he was lying flat. He had a past medical history of hypertension, hypercholesterolaemia, gout and diabetes. His medication regimen comprised ramipril 10mg OD, bumetanide 1mg BD, bisoprolol 7.5mg OD, simvastatin 40mg ON, allopurinol 100mg OD, metformin 500mg TDS, hydralazine 25mg BD, gliclazide 80mg OD and spironolactone 25mg OD

On examination, he had a heart rate of 56 bpm with a regular pulse and a blood pressure of 114/68 mmHg. Examination of the cardiovascular examination revealed the presence of a JVP of 5cm, with bilateral pitting oedema to the mid-shins. Examination of the respiratory system revealed the presence of reduced air entry bilaterally. Examination of the gastrointestinal examination was unremarkable.

Investigations revealed the following results:

Hb	162 g/l
Platelets	$125 \times 10^9/l$
WBC	$7.2 \times 10^9/l$

Na ⁺	136 mmol/l
K ⁺	3.8 mmol/l
Urea	8.6 mmol/l
Creatinine	142 μ mol/l

ECG: 54 bpm normal sinus rhythm, QRS interval 128ms, QTC 452 ms, presence of Q waves leads II, III and aVF
Chest x-ray: cardiomegaly, bilateral pleural effusions

Echocardiogram: severe left ventricular systolic impairment with residual 32% function, presence of aortic stenosis with pressure gradient 18mmHG, and presence of mild tricuspid and mitral regurgitation

Which is the next intervention most likely to improve this gentleman's symptoms and overall prognosis?

	Commence ranolazine
	Refer for angiography
	Refer for insertion of biventricular pacing therapy
	Commence ivabradine
	Refer to cardiothoracic team for consideration of valvular replacement

Dashboard

□ Question 38 of 193

□ □

A 54-year-old male business executive is referred to you after a heart murmur is detected at a medical examination he received after he transferred to a new company. He has no known past medical history or family history. He is well and leads an active lifestyle. On examination, you note a pansystolic murmur in the apex. Chest auscultation is unremarkable. An ECG demonstrates sinus rhythm at 64 beats/minute with no changes suggestive of ventricular hypertrophy. A transthoracic echocardiogram demonstrated good views with severe mitral regurgitation, preserved left ventricular function (EF 85%) and pulmonary arterial systolic pressure of 15 mmHg. Which of the following is appropriate management?

	Mitral valve replacement
	Mitral valve repair
	Percutaneous mitral valve repair (Mitraclip)
	Infective endocarditis prophylaxis and 6 monthly echocardiogram
	6 monthly echocardiogram

□ Question 40 of 193

□ □

A 72 year old gentleman has suffered from left hip pain for a number of years. His pain is there most days and worsens towards the end of the day. It is particularly severe if he has done the gardening or walked a long distance. His exercise tolerance is limited by the hip pain. Otherwise he is well and takes no medication apart from analgesia. He is a non smoker, drinks 4-6 units of alcohol per week and lives with his wife, who is also in good health.

He is scheduled for an elective left total hip replacement (THR) and attends the pre-assessment clinic. He is found to have an ejection systolic murmur that no one has previously documented. The rest of his examination is normal, his bloods are normal and a resting ECG shows normal sinus rhythm with no evidence of left ventricular hypertrophy. He is sent for a pre-operative echocardiogram. This confirms aortic stenosis with a gradient of 41 mmHg across the valve and normal left ventricular function with no hypertrophy.

In light of these findings how would you proceed?

	Continue with elective surgery but inform the GP in the discharge letter
	Postpone surgery until a cardiologist declares him fit for elective surgery
	Refer for balloon valvuloplasty
	Refer for aortic valve replacement
	Refer to a cardiologist for coronary angiogram prior to elective surgery

□ □

A 77-year-old female is electively admitted for investigation of bilateral lower limb swelling onset over the past 3 years associated with limitation of exercise as a result. Her past medical history includes bilateral pulmonary emboli in 2010 and type 2 diabetes mellitus. On examination, non-pitting bilateral lower limb oedema is noted to the high thighs without abdominal involvement. Her heart sounds are normal with no added sounds, her chest is clear. Her abdomen is soft and non-tender without ascites or superficial swelling. A transthoracic echocardiogram demonstrates normal left ventricular function but was unable to produce good views of the right heart. A CT pulmonary angiogram demonstrates no embolus, a ventilation-perfusion scan demonstrates a low probability of pulmonary emboli. Ultrasound abdomen is unremarkable. The patient undergoes a right heart catheter, demonstrating a mean pulmonary arterial pressure of 14mmHg. What is the likely cause of her lower limb swelling?

	Left heart failure
	Idiopathic pulmonary arterial hypertension
	Right heart failure
	Pelvic malignancy
	Lymphoedema

Question 43 of 193

A 30-year-old man is admitted to the Emergency Department after suffering a 'blackout' whilst at work. His colleagues report him collapsing without warning whilst waiting at the water machine. There has never happened before and he is normally fit and well.

On examination blood pressure is 102/68 mmHg, pulse 88/min, oxygen saturations 99% on room air and respiratory rate 16/min.

An ECG is taken:

© Image used on license from Dr Smith, University of Minnesota

What is the most likely diagnosis?

	Hypertrophic obstructive cardiomyopathy
	Anterior myocardial infarction
	Long QT syndrome type 1
	Arrhythmogenic right ventricular dysplasia
	Brugada syndrome

Overall score: **0%**

□ Question 44 of 193

A 76-year-old woman is brought into the Emergency Department following an episode of loss of consciousness. On more detailed review, she reveals that she has been suffering increasingly with shortness of breath on exertion, with great difficulty in managing her shopping and cleaning.

Her past medical history include right hip fracture 6 years ago after a fall walking down the stairs; this required a total hip replacement.

She takes no regular medication and has no drug allergies.

On examination, her pulse was 80 beats per minute, blood pressure 104/89 mmHg, and respiratory rate 16 breaths per minute. She had a slow rising pulse, and on auscultation of the chest there was an ejection systolic murmur heard loudest at the aortic area, and radiating to the carotid arteries.

Electrocardiogram (ECG) shows sinus rhythm and criteria for left ventricular hypertrophy.

Chest x-ray shows clear lung fields.

Transthoracic echocardiogram:

Aortic valve area	0.8 cm ² (3-4)
Transvalvular gradient	55 mmHg (0)

The diagnosis of aortic stenosis is explained to the patient, and she opts for open surgical valve replacement.

What other investigation is warranted before proceeding to aortic valve replacement?

	Exercise tolerance testing
	Dopamine stress echocardiogram
	24 hour holter ECG

	Transoesophageal echocardiogram
	Coronary angiography

Question 45 of 193

□ □

A 55-year-old man presents to the emergency department with shortness of breath.

He reports several months of worsening diarrhoea and is now passing over 10 watery motions per day.

On examination he is dyspnoeic at rest. The blood pressure is 104 / 77mmHg and the pulse rate is 90bpm and regular. Oxygen saturations are 93% on room air. Chest auscultation reveals widespread mild polyphonic wheeze and bibasal crackles. Jugular venous pressure is elevated and C-V waves are present. There is a pansystolic murmur at the left lower sternal border louder in inspiration. There is a palpable liver edge 2cm below the costal margin.

Which is the most likely underlying heart valve pathology?

	Infected platelet / fibrin deposits
	Fibrous endocardial thickening
	Sterile vegetations
	Annular dilatation
	Calcification

Question 46 of 193

A 50-year-old gentleman presented feeling dizzy and generally unwell for the last 3 days. He denied any chest pain, cough or fever but complained of increased fatigue and breathlessness. His past medical history included ischaemic heart disease, heart transplant, hypertension and diabetes. He takes the following medications: ramipril 5mg od, metformin 500mg bd, simvastatin 40mg od, amlodipine 5mg od and various immunosuppressive agents.

On examination his heart sounds were normal and chest was clear. There was only mild leg oedema. His vital signs show heart rate = 35 beats per minute, blood pressure = 90/40, SaO₂ = 95% on air, T = 36.5°C and respiratory rate = 20 breaths per minute. His ECG shows sinus bradycardia and CXR is clear. The following blood tests were obtained:

Hb	10.5 g/dl
Platelets	190 * 10 ⁹ /l
WBC	10.4 * 10 ⁹ /l

Na ⁺	135 mmol/l
K ⁺	3.6 mmol/l
Urea	8 mmol/l
Creatinine	100 µmol/l
CRP	15 mg/l

What is the next best management plan?

	Glucagon intravenous
	Atropine intravenous
	Theophylline intravenous
	Adrenaline 0.5mg intravenous

	Adrenaline 0.5mg intramuscular

Question 47 of 193

An 81-year-old man is referred to the cardiology clinic due to worsening heart failure. Over the past 12 months he has become increasingly short-of-breath, particularly upon exertion or when lying flat. He has also suffered from ankle swelling which his GP has treated with large doses of furosemide. Around 6 months ago a clinical diagnosis of heart failure was made and he is already taking bisoprolol, ramipril and atorvastatin. He was diagnosed with multiple myeloma around 3 years and has been treated with melphalan to date.

On examination his pulse is 72/min and blood pressure 98/62 mmHg. The JVP is elevated at 6cm above the angle of Louis. There are crackles in both bases and pitting oedema to his knees.

An ECG accompanies the referral:

© Image used on license from Dr Smith, University of Minnesota

What is the most likely diagnosis?

	Constrictive pericarditis
	Infective endocarditis
	Chronic pulmonary embolism
	Cardiac amyloidosis

	Hypercalcaemia-induced heart failure

Question 49 of 193

□ □

A 59-year-old woman presents to the emergency department with shortness of breath. She has been progressively getting worse over two weeks and has now started to feel short of breath on rest. She is known to have mitral valve prolapse and is awaiting surgery but has so far not been given a date. She also has polycystic ovarian syndrome, type 2 diabetes and depression. She takes metformin, sertraline and furosemide.

On examination, she looks unwell. She has bilateral crepitations with no wheeze on auscultation of her chest, a raised JVP, and a systolic murmur. A chest X-ray shows pulmonary oedema. She is treated with IV diuretics but remains breathless and hypoxic. What kind of ventilatory support would be most appropriate?

	No ventilator support is appropriate
	Negative pressure ventilation
	Intubation
	Bilevel positive airway pressure (BIPAP)
	Continuous positive airway pressure (CPAP)

□ Question 50 of 193

□ □

A 65-year-old man underwent an elective inguinal hernia repair. Due to the list running late into the evening, the patient was admitted for an overnight stay. During the night after the operation the patient was observed to have an increasing oxygen requirement and the following morning was referred to the oncall medical registrar.

The patient reported feeling progressively more short of breath since the operation, particularly when he had tried to lie down to sleep. He denied any cough, chest pain, leg swelling or palpitations. Prior to the operation the patient had been generally well although he had found that he frequently experienced double vision when reading especially in the evening. He also had noticed some difficulties when chewing tough foods in recent weeks. Past medical history was unremarkable and the patient took no regular medications.

Examination revealed a regular pulse, no elevation of jugular venous pressure and normal heart sounds. Both calves were soft and non-tender. The patient had a shallow respiratory effort and was unable to speak in full sentences. Chest expansion was reduced bilaterally, chest was resonant with vesicular breath sounds throughout. The patient had bilateral weakness of facial muscles and ptosis on prolonged upward gaze. Power of neck flexion and extension was reduced, graded as 4/5.

Basic observations:

- Blood pressure: 120 / 76 mmHg
- Heart rate: 115 beats / min
- Respiratory rate: 32 breaths / min
- Temperature: 36.8°C

Portable CXR: technically poor film due to poor inspiratory effort; clear lung fields; no pleural effusion; no upper lobe blood diversion; no free air under diaphragm.

Arterial blood gas analysis (35 % O₂)

pH	7.29
PaCO ₂	6.6 kPa
PaO ₂	8.7 kPa
Bicarbonate	18 mmol / L (reference 20.0-26.0)

Lactate	2.1 mmol / L
---------	--------------

Bedside forced vital capacity: 1.9 L

What is the most important next step in management?

	Pyridostigmine
	Referral to intensive care unit
	Reduce percentage of supplemental oxygen
	High-dose corticosteroids
	Intravenous immunoglobulin

Dashboard

Overall score: 0%

Question 51 of 193

□ □

A 54-year-old male presents to the emergency department with sudden onset palpitations and shortness of breath which began whilst he was watching television a few hours previously. He describes an odd fluttering sensation in his chest with mild dyspnoea but no chest pain. He denies having experienced this before. On systems review, he also complains of severe muscle cramps and a slight tremor in his hands over the last few days. His past medical history includes hypertension and gout for which he takes amlodipine and allopurinol. He denies any history of exertional dyspnoea but does occasionally get central chest pain on exertion for which he has not sought help. He has recently been diagnosed with small cell lung cancer and underwent his first round of chemotherapy last week; although he is unsure which drugs are being used. He used to smoke a pipe until his recent diagnosis of cancer and drinks a few measures of whisky most evenings.

On examination, his respiratory rate is 22 breaths/min and his oxygen saturations are 96% breathing two litres of oxygen. His heart rate is irregularly irregular and approximately 130 beats/min, his blood pressure is 152/78 mmHg. An ECG shows atrial fibrillation with no ischaemic changes.

What is the most likely cause for his new atrial fibrillation?

	Ischaemic heart disease
	Chemotherapy induced hypokalaemia
	Chemotherapy induced hypomagnesaemia
	Chemotherapy induced cardiomyopathy
	Alcohol

Dashboard

Question 52 of 193

A 70-year-old male presents back to hospital 3 weeks after undergoing a primary percutaneous coronary intervention for anterior STEMI. He reports 24 hour history of increasing shortness of breath, fever over 39 degrees and pleuritic chest pain, different from the pain he reported when he initially presented with his ischaemic chest pain. On examination, his calves are soft, his heart sounds are normal with no added sounds and his lungs are clear on auscultation. His serum tests reveals a mildly raised troponin and ECG that demonstrates ST elevation in V2 to V4 but no reciprocal change. Angiography was performed again, demonstrating good radiological flow with no evidence of stent thrombosis. An transthoracic echocardiogram demonstrates a mild to moderate pericardial effusion with no tamponade. What is the optimal initial treatment?

	Aspirin, clopidogrel, low molecular weight heparin as per acute coronary syndrome protocol
	Fondaparinux
	Bivaluridin
	Oral prednisolone
	Oral ibuprofen

□ Question 55 of 193

A 52-year-old man is asymptomatic but concerned about his risk of having a heart attack. His 58-year-old brother died of a myocardial infarction 2 months ago. He has a past medical history of hypertension, for which he takes perindopril and amlodipine. His sister takes tablets for diabetes and high blood pressure. He successfully quit smoking over 1 year ago and drinks approximately 2 units of alcohol per day.

On examination, his blood pressure is 130/70 mmHg and BMI is 32 kg/m².

Investigations:

haemoglobin	16g/dL (13-18)
mean corpuscular volume	90 fL (80-96)
serum cholesterol	5.0 mmol/L (<5.2)
serum LDL cholesterol	3.1 mmol/L (<3.36)
serum HDL cholesterol	1.55 mmol/L (>1.55)
fasting serum triglycerides	1.6 mmol/L (0.45-1.69)
haemoglobin A1c	5.4% (4.0-6.0)
serum aspartate aminotransferase	19 U/L (131)
plasma thyroid-stimulating hormone	2.4 mU/L (0.45-0)
estimated glomerular filtration rate (MDRD)	85 mL/min (>60)

His QRISK2 score estimates a 13% 10 year risk of myocardial infarction or stroke.

In addition to discussing lifestyle modifications, what treatment should you offer this patient?

	Aspirin

	Atorvastatin
	Indapamide
	Metformin
	Omega-3-polyunsaturated fatty acid supplements

Question 55 of 193

A 52-year-old man is asymptomatic of a myocardial infarction 2 years ago and amlodipine. His sister had a myocardial infarction 5 years ago and drinks approximately 10 units of alcohol per week.

On examination, his blood pressure is 130/80 mmHg.

Investigations:

haemoglobin

mean corpuscular volume

serum cholesterol

serum LDL cholesterol	3.1 mmol/L (<3.36)
serum HDL cholesterol	1.55 mmol/L (>1.55)
fasting serum triglycerides	1.6 mmol/L (0.45-1.69)
haemoglobin A1c	5.4% (4.0-6.0)
serum aspartate aminotransferase	19 U/L (131)
plasma thyroid-stimulating hormone	2.4 mU/L (0.45-0)
estimated glomerular filtration rate (MDRD)	85 mL/min (>60)

His QRISK2 score estimates a 13% 10 year risk of myocardial infarction or stroke.

In addition to discussing lifestyle modifications, what treatment should you offer this patient?

Aspirin

Primary prevention

(10-year cardiovascular risk $\geq 10\%$ OR
most type 1 diabetics OR
CKD if eGFR $< 60\text{ml/min/m}^2$)

Atorvastatin 20mg od

(if non-HDL has not fallen by $\geq 40\%$ then
consider titrating up to 80mg)

	Atorvastatin
	Indapamide
	Metformin
	Omega-3-polyunsaturated fatty acid supplements

Question 56 of 193

A 13 year-old girl presents with chest pain and fever.

On examination the temperature is 38.1°C, heart rate is 90 beats/minute and respiratory rate is 18 breaths/minute. The chest is clear to auscultation. There is an early diastolic murmur at the left sternal edge.

ECG reveals sinus rhythm, PR interval 210ms.

Blood tests reveal:

Hb	121 g/l
Platelets	420 * 10 ⁹ /l
WBC	9.3 * 10 ⁹ /l
Na ⁺	136 mmol/l
K ⁺	3.7 mmol/l
Urea	3.8 mmol/l
Creatinine	72 µmol/l
Bilirubin	22 µmol/l
ALP	110 u/l
ALT	53 u/l
Albumin	36 g/l
C-reactive protein	36
Antistreptolysin O antibody titre	320 units/ml

Which other sign may also be present in this patient?

	Dermatitis herpetiformis
	Erythema marginatum
	Pyoderma gangrenosum
	Vitiligo
	Livedo reticularis

□ Question 57 of 193

A 28-year-old lady pregnant lady of 37 weeks gestation presented to the Emergency Department a few hours earlier with new onset chest pain. The pain was sharp and made worse with inspiration. She also complained of rapid onset progressively increasing shortness of breath, affecting her ability to complete sentences. She denied the presence of a cough or sputum production and did not suffer from haemoptysis or calf pain. Other than a successful external cephalic version for a breech presentation five days ago and a placenta praevia which spontaneously resolved, her pregnancy was unremarkable. She was in good health with an unremarkable past medical history and normal routine investigations throughout her pregnancy. She smoked 15 cigarettes per day and did not consume alcohol. Her mother suffered from an unexplained deep vein thrombosis when she was 42 years old but otherwise her family history was unremarkable.

Initial examination revealed a heart rate of 122bpm, respiratory rate 24/min, oxygen saturations of 98% on air, a temperature of 37.6°C and a blood pressure of 112/72 mmHg. She was struggling to complete full sentences. Examination of her cardiorespiratory system revealed good air entry in both bases, a JVP of 3cm, the absence of pedal oedema and soft and non-tender calves. Examination of her gastrointestinal system was unremarkable and ultrasound auscultation revealed the presence of a fetal heartbeat.

As she was being tended to for initial investigations, her condition rapidly deteriorated. Her oxygen saturation dropped to 88% on air, and her blood pressure was recorded as 88/66mmHg. She appeared cool and clammy, and her respiratory rate increased to 32/min. The doctor tending to venepuncture noted the presence of oozing of blood from the wound. She was promptly transferred the intensive care unit and the following investigations were conducted:

Hb	101 g/l
Platelets	75 * 10 ⁹ /l
WBC	12.2 * 10 ⁹ /l

Na ⁺	136 mmol/l
K ⁺	4.8 mmol/l
Urea	14.1 mmol/l
Creatinine	158µmol/l

--	--

INR	3.9
APTT	84 s
D-Dimer	2920 ng/ml

Urinalysis: ketones ++, leucocytes/nit/prot/blood/glucose negative

Portable chest x-ray: normal appearance of heart and lung fields

ECG: sinus tachycardia 148bpm, T wave inversion leads V3-V6

Arterial blood gases on air:

pH	7.48
PaO2	5.9 kPa
PaCO2	2.2 kPa
BE	1
HC03	24 mmol/l

She was commenced on 15 litres/min oxygen via non-rebreathe mask, and an arterial line and central venous line were sited, as well as the presence of two large bore peripheral cannulae. She was immediately commenced on 2 litres of Hartmann's solution stat.

What is the most likely diagnosis?

	Pulmonary embolus
	Septic shock
	Peripartum cardiomyopathy
	Aortic dissection
	Amniotic fluid embolus

Dashboard

□ Question 58 of 193

A 72-year-old male smoker with a history of hypertension, heart failure and poorly controlled type 2 diabetes mellitus presents with sudden onset shortness of breath of a few hours duration. He describes this as a tight sensation in his chest and pain while trying to breathe. He is wheelchair bound due to weakness in both lower limbs and spends most of his time either lying in bed reading or sitting watching TV. He commenced a course of antibiotics for suspected lower limb cellulitis 3 days ago.

On examination, he has bilaterally reduced chest expansion. His lower limbs show evidence of pitting oedema up to the mid calves, which is more pronounced on the right side with a patch of dusky purple discolouration.

Lab reports reveal:

Hb	180 g/l
WBC	$10 \times 10^9/l$
Plt	$375 \times 10^9/l$
Urea	7.9 mmol/l
Creatinine	190 μ mol/l
Na+	133 mmol/l
K+	4.1 mmol/l
Albumin	28 g/l

Urine routine examination showed proteinuria 2+

ECG shows sinus tachycardia.

Chest X-ray shows clear lung fields with no mass lesion.

Which is the most appropriate next diagnostic investigation?

--	--

	D-dimer assay
	CT pulmonary angiography
	Ventilation-perfusion scan
	Right heart catheterization
	Pulmonary arteriography

Question 59 of 193

□ □

A 72-year-old gentleman is admitted with syncope and palpitations. He is known to have atrial fibrillation and is on flecainide and warfarin. His past medical history also includes benign prostatic hypertrophy and essential thrombocytosis.

His other medications include tiotropium 18 micrograms OD, tamsulosin 400 micrograms OD, ramipril 2.5mg and simvastatin 40mg. He has recently stopped a tablet due to shortness of breath but cannot remember what it was.

On arrival, he is tachycardic with a heart rate of 215 /min. He is alert. He denies chest pain but is aware of some shortness of breath. He is attached to a 3-lead cardiac monitor which shows a narrow complex tachycardia of 210-220 beats per minute. It is difficult to tell on the monitor however it appears regular. A 12-lead ECG confirms a regular narrow complex tachycardia with a ventricular rate of 215/min.

What is the most likely diagnosis?

	Atrial fibrillation
	Atrial flutter with 1:1 conduction
	Atrial flutter with variable conduction
	Atrio-ventricular re-entry tachycardia (AVRT)
	Atrio-ventricular nodal re-entry tachycardia (AVNRT)

□ Question 61 of 193

A 66-year-old gentleman presented to the Emergency Department complaining of severe abdominal pain for the last day. The pain occurred immediately after he ate, and he described it as an excruciating pain in the central of his abdomen. It lessened during periods of starvation, and a few hours ago passed dark red blood within his stools on one occasion, leading to his admission. His bowels were otherwise normal and prior to the pain had been relatively well in himself. In addition, he had been feeling unwell for the last couple of days, complaining of night sweats and tiredness. His past medical history comprised angina which had been confirmed three days ago upon undergoing a coronary angiogram which demonstrated diffuse triple vessel disease. In addition, he had a past medical history of hypertension, hypercholesterolaemia and COPD. He smoked 30 cigarettes per day for 25 years and did not consume alcohol and was taking amlodipine 5mg OD, ramipril 7.5mg OD, bisoprolol 2.5mg OD, atorvastatin 20mg OD, beclometasone 200mcg BD & salbutamol PRN.

Examination revealed an obese gentleman with a temperature of 37.6°C, a heart rate of 118bpm, respiratory rate of 18/min and blood pressure of 142/82 mmHg. Examination of his cardiovascular and respiratory systems revealed the absence of his pedal pulses bilaterally, with no evidence of ulceration or gangrene. A purpuric rash was noted on both halluxes.

Initial investigations revealed the following results:

Hb	122 g/l
Platelets	132 * 10 ⁹ /l
WBC	11.2 * 10 ⁹ /l
Eosinophils	0.6 * 10 ⁹ /l
ESR	52 mm/hr

Na ⁺	136 mmol/l
K ⁺	5.8 mmol/l
Urea	13.3 mmol/l
Creatinine	158 µmol/l

CRP	38 mg/l

Urinalysis protein +, otherwise nil else

ECG: heart rate 118bpm sinus tachycardia, Q waves II/III/aVR

Blood results 4 weeks ago (done by GP when titrated ramipril)

Na ⁺	142 mmol/l
K ⁺	4.8 mmol/l
Urea	6.6 mmol/l
Creatinine	86 µmol/l

Which one of the following is the most likely diagnosis?

	Contrast induced nephropathy
	Cholesterol atheroemboli
	Polyarteritis nodosa
	Infective endocarditis
	Microscopic polyangiitis

□ Question 64 of 193

□ □

A 50 year old Caucasian female on holiday from Australia presents to the walk-in urgent care centre with four day history of left sided temporal headache, which is persistent and of gradual onset. In addition, she complains of double vision as well. She is known to have migraines but is relatively well-controlled. She is normally independent with no significant family history. She takes no regular medications except the oral contraceptive pill. On examination, you note a left sided loss of the afferent papillary reflex. She also has a loss of vertical gaze and is unable to adduct her left eye. She has a reduced sensation to light touch on the left forehead and cheek, not crossing the midline. What is the diagnosis?

	Left space-occupying lesions
	Multiple sclerosis
	Right MCA territory ischaemic infarct

□ Question 64 of 193

□ □

A 50 year old Caucasian female on holiday from Australia presents to the walk-in urgent care centre with four day history of left sided temporal headache, which is persistent and of gradual onset. In addition, she complains of double vision as well. She is known to have migraines but is relatively well-controlled. She is normally independent with no significant family history. She takes no regular medications except the oral contraceptive pill. On examination, you note a left sided loss of the afferent papillary reflex. She also has a loss of vertical gaze and is unable to adduct her left eye. She has a reduced sensation to light touch on the left forehead and cheek, not crossing the midline. What is the diagnosis?

	Left space-occupying lesions
	Multiple sclerosis
	Right MCA territory ischaemic infarct
	Cavernous sinus thrombosis
	Migraine with aura

□ Question 65 of 193

□ □

A 67-year-old with a history of ischaemic heart disease (primary percutaneous intervention for a STEMI three years ago) is admitted with a pyrexia of unknown origin. On examination his pulse is 96/min, temperature 38.2°C and blood pressure 104/66 mmHg. A systolic murmur is noted but auscultation of the chest is unremarkable. His post-myocardial infarction echocardiogram three years ago showed no valvular disease. Chest x-ray is normal and urine dipstick shows blood ++. A petechial rash is noted on his hands and legs. A presumptive diagnosis of infective endocarditis is made and empirical treatment with IV amoxicillin and gentamicin given. Two days later blood cultures show a coagulase-negative staphylococcus. What is the most appropriate action with respect to antibiotic therapy?

	Switch to flucloxacillin
	Switch to flucloxacillin + vancomycin + rifampicin
	Make no changes to treatment
	Switch to flucloxacillin + vancomycin
	Switch to flucloxacillin + rifampicin

Question 66 of 193

A 26-year-old patient comes into the Emergency Department in cardiac arrest. The paramedics tell you that she was pulled out of a lake by friends after she had suddenly become unresponsive while swimming. Her friends started cardiopulmonary resuscitation (CPR) at the scene. On arrival, the paramedics noted that the patient was in Ventricular Fibrillation (VF). The patient was defibrillated, given IV amiodarone and adrenaline. Her friends tell you she has no significant past medical history and was always fit and well until this point.

Despite continued attempts to resuscitate the patient, she dies in the Emergency Department. A post-mortem is carried out which is normal.

What is the most likely diagnosis?

	Hypertrophic Obstructive Cardiomyopathy (HOCM)
	Long QT1 Syndrome
	Long QT3 Syndrome
	Right Arrhythmogenic Ventricular Dysplasia (RAVD)
	Wolf-Parkinson White Syndrome

Question 68 of 193

An 82-year-old presents with suprapubic discomfort. He reports urgency but has been unable to pass any urine for over 24 hours. Three months ago, he underwent a third failed transurethral resection of the prostate for benign prostatic hypertrophy (PSA was normal). His past medical history includes hypertension, type 2 diabetes mellitus, chronic kidney disease (baseline creatinine 150 $\mu\text{mol/l}$) previous MI in 2007 and 2010. He remains relatively active, with an exercise tolerance of 500 yards. On examination, his mucous membranes are moist, his peripheries are warm and his JVP at 3 cm above the angle of Louis. His heart sounds and chest are unremarkable. His abdomen is tender and distended in the suprapubic region. On insertion of a urethral catheter, 900mls of residual urine is noted. His blood tests are as follows:

Hb	115 g/l
Platelets	$282 \times 10^9/\text{l}$
WBC	$6.8 \times 10^9/\text{l}$

Na^+	144 mmol/l
K^+	5.8 mmol/l
Urea	12.1 mmol/l
Creatinine	201 $\mu\text{mol/l}$
Troponin T	0.08 (normal <0.03)

His ECG demonstrates left bundle branch block (old) and first-degree heart block at a rate of 49 beats/ minute and regular. What is the appropriate management?

<input type="checkbox"/>	Treat as acute coronary syndrome only
<input type="checkbox"/>	Intravenous fluids only
<input type="checkbox"/>	Monitor renal function and consider long term catheter only
<input type="checkbox"/>	Treat as acute coronary syndrome, monitor renal function and consider long term catheter

	Treat as acute coronary syndrome, intravenous fluids, monitor renal function and consider long term catheter

Question 71 of 193

A 23-year-old woman presents with chest pain. It progressed over an hour whilst at home and watching television. She describes it as sharp in nature and rates it seven out of ten in severity. She has not had any pain similar to this before but is concerned as she thinks it might be a pulmonary embolus. She was warned to monitor for symptoms of a pulmonary embolism two years ago when she was diagnosed with a right sided deep vein thrombosis in her right popliteal vein. The deep vein thrombosis was attributed to use of the oral contraceptive pill; this was stopped and she was treated with warfarin for three months. She has had no more clots as far as she is aware since then. She is currently taking no regular medications but has found that ibuprofen significantly helps with her chest pain. She has recently had coryzal symptoms.

On examination, she appears comfortable, but she has recently had 400mg of ibuprofen. Her observations show a heart rate of 76/min, respiratory rate of 14/min, a temperature of 38.2°C and a blood pressure of 123/75mmHg. An ECG shows widespread ST-elevation and PR depression. Blood tests are pending and an echocardiogram is requested. She is suspected of having acute pericarditis. What would indicate a poor prognosis?

	Fever
	ST elevation on ECG
	PR depression on ECG
	Improvement with ibuprofen
	Elevated inflammatory markers

Dashboard

□ Question 76 of 193

You review a 65 year-old male who was admitted yesterday. He is a diabetic gentleman who was admitted with a non-ST elevation myocardial infarction and subsequent flash pulmonary oedema. He has been treated with aspirin, clopidogrel, fondaparinux and intravenous furosemide. He is achieving a good diuresis - producing 100mls of urine per hour.

You have been asked to see him as he continues to have significant breathlessness but no ongoing chest pain. His blood pressure is 92/87mmHg and oxygen saturations are 83% on 65% humidified oxygen. He has bibasal crepitations and JVP is raised. His ABG results are as follows:

pH	7.32
pCO ₂	4.6kPa
pO ₂	7.9kPa

What would be your next clinical intervention?

<input type="checkbox"/>	Start non-invasive ventilation
<input type="checkbox"/>	Start continuous positive airway pressure ventilation (CPAP)
<input type="checkbox"/>	Refer for angiography and primary coronary intervention
<input type="checkbox"/>	Start a tirofiban infusion
<input type="checkbox"/>	Start a GTN infusion

Dashboard

□ Question 77 of 193

A 79-year-old woman is reviewed in cardiology clinic as part of the ongoing assessment for possible intervention for severe aortic stenosis. The patient had been diagnosed with severe aortic stenosis 4 months previously, after experiencing progressive exertional breathlessness and reduced exercise tolerance. At her initial review at cardiology clinic, the patient had expressed interest in undergoing intervention for aortic stenosis: either surgical aortic valve replacement (SAVR) or transcatheter aortic valve insertion (TAVI). Subsequently, the patient had undergone a variety of investigations to assess her suitability for the above procedures.

The patient had a good functional status, leaving independently with her daughter and still participating in a wide range of community activities. The patient had a long-standing diagnosis of hypertension and had suffered a left cortical stroke 3 years previously. In addition, the patient had chronic obstructive pulmonary disease, although she had stopped smoking 30 years previously. The patient's regular medications were amlodipine, ramipril, clopidogrel, simvastatin and an ipratropium inhaler. The patient used a salbutamol inhaler as required. The patient had no known drug allergies.

A summary of the investigations undergone by the patient is given below.

Haemoglobin	128 g / dL
Mean cell volume	87.1 fl
White cell count	6.3×10^3 / microlitre
Platelets	324×10^3 / microlitre
Urea	5.3 mmol / L
Creatinine	124 micromol / L
Sodium	136 mmol / L
Potassium	4.6 mmol / L

Investigation	Result
Transthoracic	Severe aortic stenosis (valve area 0.85 cm ²); no other valve disease; normal systolic function;

echocardiogram	no anatomic contraindications to TAVI
Coronary angiography	No evidence of coronary artery disease
Iliofemoral angiography	Severe calcification and tortuosity of iliac arteries; unsuitable for transfemoral TAVI
Pulmonary function tests	Moderate obstructive lung disease

Following the above assessment, surgical aortic valve replacement was estimated to carry a 4.1 % risk of mortality and 3.7 % risk of permanent stroke (intermediate risk). No contraindications to transapical transcatheter aortic valve insertion were identified.

What is the recommended choice of intervention for the patient's aortic stenosis?

<input type="radio"/>	Surgical aortic valve replacement and transcatheter aortic valve insertion inappropriate
<input type="radio"/>	Surgical aortic valve replacement with mechanical valve
<input type="radio"/>	Transapical transcatheter aortic valve insertion

□ Question 77 of 193

A 79-year-old woman is reviewed in cardiology clinic as part of the ongoing assessment for possible intervention for severe aortic stenosis. The patient had been diagnosed with severe aortic stenosis 4 months previously, after experiencing progressive exertional breathlessness and reduced exercise tolerance. At her initial review at cardiology clinic, the patient had expressed interest in undergoing intervention for aortic stenosis: either surgical aortic valve replacement (SAVR) or transcatheter aortic valve insertion (TAVI). Subsequently, the patient had undergone a variety of investigations to assess her suitability for the above procedures.

The patient had a good functional status, leaving independently with her daughter and still participating in a wide range of community activities. The patient had a long-standing diagnosis of hypertension and had suffered a left cortical stroke 3 years previously. In addition, the patient had chronic obstructive pulmonary disease, although she had stopped smoking 30 years previously. The patient's regular medications were amlodipine, ramipril, clopidogrel, simvastatin and an ipratropium inhaler. The patient used a salbutamol inhaler as required. The patient had no known drug allergies.

A summary of the investigations undergone by the patient is given below.

Haemoglobin	128 g / dL
Mean cell volume	87.1 fl
White cell count	6.3×10^3 / microlitre
Platelets	324×10^3 / microlitre
Urea	5.3 mmol / L
Creatinine	124 micromol / L
Sodium	136 mmol / L
Potassium	4.6 mmol / L

Investigation	Result
Transthoracic	Severe aortic stenosis (valve area 0.85 cm ²); no other valve disease; normal systolic function;

echocardiogram	no anatomic contraindications to TAVI
Coronary angiography	No evidence of coronary artery disease
Iliofemoral angiography	Severe calcification and tortuosity of iliac arteries; unsuitable for transfemoral TAVI
Pulmonary function tests	Moderate obstructive lung disease

Following the above assessment, surgical aortic valve replacement was estimated to carry a 4.1 % risk of mortality and 3.7 % risk of permanent stroke (intermediate risk). No contraindications to transapical transcatheter aortic valve insertion were identified.

What is the recommended choice of intervention for the patient's aortic stenosis?

	Surgical aortic valve replacement and transcatheter aortic valve insertion inappropriate
	Surgical aortic valve replacement with mechanical valve
	Transapical transcatheter aortic valve insertion
	Surgical aortic valve replacement with bioprosthetic valve
	Transfemoral transcatheter aortic valve insertion

Question 79 of 193

□ □

A 55-year-old man with type 2 diabetes comes to the Emergency department with symptoms of worsening cardiac failure. Current medication includes metformin and empagliflozin for blood glucose control, ramipril, doxazosin, furosemide, aspirin and atorvastatin. His blood pressure is 112/70 mmHg, his pulse is 80 beats per minute and regular. There are bilateral crackles to the mid zones on auscultation of the chest, and he has pitting oedema to the mid-shins bilaterally.

Investigations

Na ⁺	138 mmol/l
K ⁺	4.5 mmol/l
Urea	6.2 mmol/l
Creatinine	112 µmol/l

Which of the following medications would you discontinue?

	Atorvastatin
	Doxazosin
	Empagliflozin
	Metformin
	Ramipril

□ Question 82 of 193

A 19-year-old girl was seen in clinic with lethargy, weakness worsening over the past 4 weeks. She also complains of recurrent muscle cramps in her legs, causing her to have trouble sleeping. On further questioning she admits to urinary frequency, passing urine up to ten times a day, and feels dehydrated all the time. She also mentions that her periods which were usually irregular, have stopped 4 months ago.

On examination, she is thin, with a body mass index of 17kg/m². Her heart rate is 88 bpm and blood pressure is 108/86 mmHg.

C Reactive protein	2mg/l
Haemoglobin	158 g/l
White cell count	7.6 x 10 ⁹ /L
Na+	136 mmol/l
K+	2.9 mmol/l
Urea	7.2 mmol/l
Creatinine	108 µmol/l
Corrected calcium	2.42 mmol/l

Venous blood gas result

pH	7.532
Bicarbonate	37mmol/l

What would be the next most useful investigation?

	Transvaginal ultrasound (TVUS) of the ovaries
	Urine diuretic assay

	Early morning cortisol
	Serum renin and aldosterone levels
	Fasting blood glucose levels

Dashboard

Question 83 of 193

□ □

A 43-year-old lady with a history of schizophrenia presents to the emergency department with palpitations, headaches and dizziness for 3 days. She says that she can feel her heart pounding after which she becomes dizzy and feels faint. She has noted these bouts about three to four times per day. She does not suffer from diabetes and is not hypertensive.

Regarding her headaches, she has had them for a long period of time and is quite convinced that there is some sort of sinister problem with her brain, although her doctors do not believe so. She has a younger sister who has had epilepsy for the last 15 years.

She was diagnosed as having a UTI 4 days ago which is currently being treated with ciprofloxacin. Her medication history includes olanzapine and occasional paracetamol for her headaches.

On examination, her pulse was 135 bpm with an irregular rhythm. Blood pressure was 90/60mmHg. Her systemic examination was unremarkable.

Attachment to a cardiac monitor revealed runs of ill sustained polymorphic tachycardia. She was immediately given IV lidocaine to which there was no response.

Which is the most appropriate next step in management?

	Immediate DC cardioversion
	IV amiodarone
	IV flecainide
	IV magnesium sulphate
	IV labetalol

Overall score: **0%**

Question 87 of 193

A 68 year-old man with a history of ischaemic heart disease and type 2 diabetes mellitus is 2 days post right curative hemicolectomy for bowel malignancy.

He has developed chest pain and shortness of breath. The surgical team have requested an urgent medical review.

On examination the patient appears distressed and is complaining of chest pain and breathlessness. Capillary refill time is 5 seconds centrally. The pulse rate is 200bpm and the blood pressure is 87/45mmHg. Oxygen saturations are 92% on fiO2 0.4 via Venturi mask.

There are crackles to the midzones bilaterally on chest auscultation.

A 12-lead ECG reveals a regular broad complex tachycardia with a monomorphic waveform.

Blood results from the morning reveal:

Hb	129 g/l
Platelets	564 * 10 ⁹ /l
WBC	15.8 * 10 ⁹ /l
Na ⁺	128 mmol/l
K ⁺	3.3 mmol/l
Urea	12.9 mmol/l
Creatinine	101 µmol/l
Bilirubin	27 µmol/l
ALP	125 u/l
ALT	34 u/l
Albumin	36 g/l

What is the most appropriate initial management?

	Adenosine 6mg IV
	Amiodarone 300mg IV
	Magnesium sulphate 2g IV
	Synchronised DC shock
	Metoprolol 5mg IV

Question 90 of 193

□ □

A 50-year-old lady presented with a 2 month history of breathlessness on exertion, increasing leg swelling and more recently a rash across her face. She was found to be in congestive heart failure, acute kidney injury and she was being treated with diuretics. Her echocardiogram showed severe left ventricular dysfunction. A few days into her admission she sustained a ventricular fibrillation cardiac arrest, which was successfully treated and the patient was started on amiodarone and betablocker. Her blood tests following the cardiac arrest did not show any electrolyte abnormalities. She also had a coronary angiogram which revealed normal coronary arteries. Subsequently, she was diagnosed with systemic lupus erythematosus and associated lupus myocarditis and she started appropriate immunosuppressive treatment for lupus.

What would be the best management for her ventricular fibrillation cardiac arrest?

	Continue amiodarone indefinitely
	Implantable cardioverter defibrillator immediately and stop amiodarone
	Continue amiodarone and medical treatment of lupus and review progress in clinic to decide about implantable cardioverter defibrillator
	Implantable cardioverter defibrillator immediately and amiodarone indefinitely
	None of the above

□ Question 91 of 193

□ □

A 53-year-old Syrian refugee is referred to the cardiology clinic by her GP with dyspnoea and increasing peripheral oedema. Her past medical history is significant for rheumatic fever as a child. She gives a six month history of increasing dyspnoea on exertion. Her dyspnoea is now so severe that she has marked limitation in activity, being only able to walk 30 meters before stopping because of symptoms. She experiences no chest pain but tells you that she has taken to sleeping in a chair at night and has a chronic cough productive of pink sputum. More recently, she has awoken breathless from sleep terrified that she is going to die. On examination she has clinical evidence of severe mitral stenosis. She has an irregularly-irregular pulse and an ECG confirms atrial fibrillation at a rate of 89 bpm. Auscultation reveals a mid-diastolic murmur, an opening snap and a loud P2. She has bibasal crepitations and pitting oedema to below the knee. Her echo confirms severe mitral stenosis with a mitral valve area of 0.7cm² and a mean gradient of 12mmHg. There is no evidence of mitral regurgitation and the sonographer comments that she has favourable mitral valve morphology. Assuming a TOE excludes a left apical thrombosis, how should this lady be managed?

	Diuresis, anticoagulate with one of the oral direct thrombin inhibitors/ factor Xa inhibitors and percutaneous mitral valve balloon valvotomy
	Diuresis, anticoagulate with warfarin and refer for mitral valve replacement
	Diuresis, anticoagulate with warfarin and repeat echo in three months time
	Diuresis, anticoagulate with one of the oral direct thrombin / factor Xa inhibitors and refer for mitral valve replacement
	Diuresis, anticoagulate with warfarin and percutaneous mitral valve balloon valvotomy

□ Question 91 of 193

□ □

A 53-year-old Syrian refugee is referred to the cardiology clinic by her GP with dyspnoea and increasing peripheral oedema. Her past medical history is significant for rheumatic fever as a child. She gives a six month history of increasing dyspnoea on exertion. Her dyspnoea is now so severe that she has marked limitation in activity, being only able to walk 30 meters before stopping because of symptoms. She experiences no chest pain but tells you that she has taken to sleeping in a chair at night and has a chronic cough productive of pink sputum. More recently, she has awoken breathless from sleep terrified that she is going to die. On examination she has clinical evidence of severe mitral stenosis. She has an irregularly-irregular pulse and an ECG confirms atrial fibrillation at a rate of 89 bpm. Auscultation reveals a mid-diastolic murmur, an opening snap and a loud P2. She has bibasal crepitations and pitting oedema to below the knee. Her echo confirms severe mitral stenosis with a mitral valve area of 0.7cm² and a mean gradient of 12mmHg. There is no evidence of mitral regurgitation and the sonographer comments that she has favourable mitral valve morphology. Assuming a TOE excludes a left apical thrombosis, how should this lady be managed?

	Diuresis, anticoagulate with one of the oral direct thrombin inhibitors/ factor Xa inhibitors and percutaneous mitral valve balloon valvotomy
	Diuresis, anticoagulate with warfarin and refer for mitral valve replacement
	Diuresis, anticoagulate with warfarin and repeat echo in three months time
	Diuresis, anticoagulate with one of the oral direct thrombin / factor Xa inhibitors and refer for mitral valve replacement
	Diuresis, anticoagulate with warfarin and percutaneous mitral valve balloon valvotomy

Question 92 of 193

□ □

A 57-year-old man is presents after incidental finding of a systolic murmur. He is normally fit, well and active. His past medical history includes hypertension, gout and appendicectomy. Observations are normal and a transthoracic echocardiogram demonstrates aortic stenosis with the surface area of the aortic valve at 0.8cm² and a pressure gradient of 53mmHg. The ejection fraction is 64%. He denies any exertional symptoms including shortness of breath and chest pain. What is the most appropriate management plan?

	Review in six months
	Exercise test
	Transcatheter aortic valve implantation (TAVI)
	Aortic valve replacement
	Trans-oesophageal echocardiogram

Question 93 of 193

A 67 year old male presents with increasing chest pain on exertion over the past 3 weeks, stopping him from going to work. His past medical history includes hypertension, type 2 diabetes mellitus, sick sinus syndrome, recent abstinence from alcohol after history of excess (with an episode of acute liver decompensation 9 months ago) and stable angina. He previously tried isosorbide mononitrate but reported significant headaches and facial flushing. He has not previously suffered myocardial infarctions, with a recent echo demonstrating 70% ejection fraction. An ECG demonstrates first degree heart block with normal QRS complexes at 50 beats/ minute, blood pressure is 140/76 mmHg. He currently takes bisoprolol 5mg OD alone and has been using his GTN spray with increasing frequency without effect. What is the next appropriate management step?

	Reperfusion therapy with coronary artery bypass graft or percutaneous coronary intervention
	Ranolazine
	Ivabridine
	Diltiazem
	Nicorandil

□ Question 94 of 193

A 66-year-old lady attended a cardiology clinic for follow up after a recent hospital admission with pulmonary oedema. She continued to experience significant shortness of breath at rest with exercise tolerance that was limited to a few steps around the house. She had a previous medical history of hypertension, diabetes and myocardial infarction 5 years previously treated with percutaneous coronary intervention. Her medications comprised of bisoprolol 10mg, ramipril 10mg, furosemide 80mg twice daily, spironolactone 25mg, simvastatin 40mg, metformin 1g twice daily and aspirin 75mg. On examination she appeared breathless, the jugular venous pressure was elevated at 7cm, there were bibasal fine crepitations and moderate pitting oedema to her knees. Her heart rate was 68 beats per minute and blood pressure was 95/65mmHg.

Investigations:

Haemoglobin	115 g/L
White cell count	$5.6 \times 10^9/\text{L}$
Platelet Count	$268 \times 10^9/\text{L}$
Serum sodium	132mmol/L
Serum potassium	4.3mmol/L
Serum urea	6.7mmol/L
Serum creatinine	68micromol/L

Electrocardiogram: normal sinus rhythm. Rate 65 beats per minute. QRS duration 155ms. No acute ST changes.

Echocardiography: left ventricular ejection fraction of 30%. No significant valvular abnormalities.

Coronary angiography: Patent left anterior descending coronary artery stent. Minor diffuse coronary artery disease.

What is the most appropriate next management step?

	Increase dose of furosemide

	Cardiac resynchronisation therapy
	Coronary artery bypass graft
	Start amlodipine
	Home oxygen

□ Question 95 of 193

□ □

A 24-year-old male presents to the emergency department with a collapse. The previous night he had been out drinking heavily with his friends in a nightclub. A friend attends with him and states that some of the lads had taken MCAT (Mephedrone) but he is unsure whether Michael also took MCAT. Michael felt well when he woke up but realised that he was late for his football match so rushed out of the house without any breakfast. He had just scored the first goal of the match when he collapsed. When he came around he complained of palpitations.

His past medical history includes asthma and hay fever for which he takes regular antihistamines. During the ambulance ride to hospital the paramedic performed some observations and an ECG. He was found to have a blood glucose of 3.6 and was given some GlucoGel and a biscuit. Other observations included a blood pressure of 90/60 mmHg, heart rate of 135/min which was irregular, irregular in character, respiratory rate of 16/min, afebrile.

The emergency department doctor reviewed the ECG and diagnosed atrial fibrillation with a fast ventricular response and prescribed digoxin in view of his asthma history and blood pressure readings. The patient had a normal QTc. Five minutes later the cardiac monitor showed a broad complex tachycardia and Michael became unresponsive.

What was the cause of the patient's collapse?

	Hypertrophic cardiomyopathy (HCM)
	MCAT related arrhythmia
	Wolff-Parkinson-White syndrome
	Alcohol induced atrial fibrillation
	Torsades de pointes

Dashboard

Question 96 of 193

□ □

A 52-year-old lady was admitted with sudden onset central chest pain and breathlessness. Her past medical history included hypertension, atrial fibrillation and she was a smoker of 20 cigarettes a day. She lived alone after having recently split up with her husband which had been a difficult few weeks. Her friend had been staying with her occasionally during this difficult period.

She had a family history of ischaemic heart disease. She had recently complained to her friend of a cold that was now passing. Medications included aspirin 75mg OD and bisoprolol 5mg OD. Her friend called 999 and she was admitted directly to the angiogram suite as the paramedics noticed that her ECG showed ST elevation in the anterior chest leads.

Her angiogram showed mild coronary atherosclerosis but an akinetic left ventricle. Her troponin T was significantly elevated at 7800ng/L (normal < 14).

What is the most likely diagnosis?

	Pericarditis
	Myocardial infarction
	Embolic event
	Takotsubo cardiomyopathy
	Pneumothorax

Question 97 of 193

A 46-year-old man presents to the Emergency Department with chest pain. This started earlier in the day after a particularly stressful meeting in the morning. He has no past medical history of note other than a brief episode of depression three years. The pain is described as a 'tightening' and 'pounding' and is associated with nausea and a headache.

On examination the heart rate is 96/min, blood pressure 140/92 mmHg and respiratory rate 18/min.

An ECG is taken:

© Image used on license from Dr Smith, University of Minnesota

What does the ECG show?

	Hypertrophic obstructive cardiomyopathy
	Arrhythmogenic right ventricular dysplasia
	Brugada syndrome
	Subarachnoid haemorrhage
	Posterior myocardial infarction

□ □

A 45 year-old man is referred to the nephrologists for investigation of chronic kidney disease. He has a past medical history of hypertension, type 2 diabetes, and Parkinsons disease, and his medication comprises ramipril, metformin, and bromocriptine.

Review of blood tests shows that the glomerular filtration rate (GFR) has steadily fallen from 85 to 44ml/min/1.73m² over the last year.

On questioning, his only symptom is chronic back pain which has been getting worse over the last year. On examination, both kidneys are easily palpable.

Routine investigations are as follows:

Hb	12.1 g/dl
MCV	94.2 fl
Platelets	264 x10 ⁹ /l
WCC	7.1 x10 ⁹ /l
Na	137mmol/l
K	4.6 mmol/l
Urea	13.8 mmol/l
Creatinine	157 mol/l
eGFR	44 ml/min/1.73m ²
ALT	24 IU/l
ALP	78 IU/l
Bilirubin	6 mol/l
Albumin	37 g/l

Total protein	64 g/l
Serum protein electrophoresis	pending
Urine dipstick	negative for blood, protein, leucocytes, and nitrites

Abdominal ultrasound shows bilateral hydronephrosis.

What is the most likely cause of his chronic kidney disease?

	Multiple myeloma
	Diabetic nephropathy
	Bladder cancer
	Retroperitoneal fibrosis
	Autosomal dominant polycystic kidney disease

Dopaminergic neuron of the substantia nigra

□ Question 102 of 193

A 56-year-old male was admitted to the Medical Admission Unit with shortness of breath. It was of relatively sudden onset having developed over the course of the last five days. It initially occurred with severe exertion but gradually progressed such that by the time of admission he was breathless at rest with significant orthopnoea and paroxysmal nocturnal dyspnoea. His past medical history included angina for which he was awaiting hospital investigation, hypertension, hypercholesterolaemia and a transient ischaemic attack three years ago. Over the course of the last few weeks, he had been seeing his GP with poor blood pressure control. In addition to felodipine M/R 5mg OD, indapamide 25mg OD and bisoprolol 7.5 mg OD the GP introduced ramipril 2.5mg OD two weeks ago. His other medication comprised of aspirin 75 mg OD, dipyridamole M/R 200mg BD, GTN spray PRN and simvastatin 40mg OD. He smoked 40 cigarettes per day and consumed 38 units of alcohol per week.

On examination to the Medical Admission Unit, he was short of breath at rest, with a respiratory rate of 26/min and oxygen saturations of 92% on air. His blood pressure was 158/78 mmHg and heart rate 54 bpm. Examination of the cardiovascular system revealed the presence of normal heart sounds, a JVP of 4 cm and the absence of pedal oedema. Examination of the respiratory system revealed bibasal crackles, whilst examination of the gastrointestinal and neurological systems was unremarkable.

Initial investigations revealed the following results:

Na ⁺	138 mmol/l
K ⁺	4.6 mmol/l
Urea	18.9 mmol/l
Creatinine	245 µmol/l
Glucose	5.7 mmol/l
Troponin I	<0.05
CRP	2 mg/l
ESR	6 mm/hr

ECG: normal sinus rhythm 56 bpm

Chest x-ray: bilateral pulmonary oedema, normal heart diameter

Urinalysis: NAD

Transthoracic echocardiogram: normal systolic function, presence of aortic stenosis with pressure gradient of 18mmHg, as well as mild mitral regurgitation.

Treatment was commenced with IV furosemide 80mg OD and GTN, as well as IV diamorphine 2.5 mg OD with excellent effect and the patient recovered over the next two days.

What is the next best investigation to determine the cause of this gentleman's symptoms?

	Coronary angiography
	Renal angiography
	Myocardial perfusion scanning
	Renal magnetic resonance angiography
	No further investigations required

□ □

A 75 year old male presents with increasing chest pain on exertion. He was first diagnosed with stable angina 7 years ago. His past medical history includes hypercholesterolaemia and hypertension. His drugs history includes bisoprolol and diltiazem, which he has been taking for the past 3 years. A recent angiogram was arranged as an outpatient by his GP, demonstrating stenoses in his left circumflex artery, distal right coronary artery and mid-left anterior descending artery. What is the most appropriate long-term treatment of choice for his angina?

	Coronary artery bypass graft
	Percutaneous coronary intervention with 3 stents
	Addition of ivrabradine
	Addition of nicorandil
	Addition of ranolazine

Question 104 of 193

□ □

A 73-year-old is referred to the pulmonary hypertension team after undergoing an echocardiogram. She had initially been admitted after a 4-day history of exertional dyspnoea. A chest x-ray revealed bilateral pulmonary oedema. She demonstrated acute ischaemic changes on her ECG. Her past medical history includes type 2 diabetes mellitus, hypertension, hypercholesterolaemia and a previous NSTEMI in 2010. An echocardiogram demonstrated moderate to severe LV dysfunction, with a pulmonary arterial pressure of 83 mmHg (normal <25 mmHg). What is the most appropriate next diagnostic investigation?

	No further investigations for pulmonary hypertension
	V/Q scan
	CTPA
	Right and left heart catheterisation
	Lung function tests

Question 107 of 193

An 18-year-old man presents with difficulty in breathing while trying out for his university frisbee team. He has always had a mild exertional dyspnoea in childhood but put it down to being unfit as a child. There is no family history of sudden death or any other cardiac problems.

On examination his respiratory rate is 18, oxygen saturations are 96% on air, heart rate of 70 bpm, and blood pressure of 126/76 mmHg. He is slender, and on cardiovascular examination, there is a systolic ejection murmur heard in the left second intercostal space at the sternal edge. ECG demonstrates sinus rhythm, with tall peaked P waves and a prolonged PR interval.

He undergoes a cardiac catheterisation procedure, results are as follows:

	Pressures	Oxygen saturation
Superior Vena Cava (SVC)	- 75%	
Inferior Vena Cava (IVC)	-	78%
Right Atrium	-	90%
Right Ventricle	50/8mmHg	89%
Pulmonary Artery	40/15mmHg	90%
Left Atrium	-	98%
Left Ventricle	130/15mmHg	95%
Aorta	126/72mmHg	95%

What is the most likely diagnosis?

<input type="checkbox"/>	Ostium Secundum Atrial Septal Defect
<input type="checkbox"/>	Ostium Primum Atrial Septal Defect
<input type="checkbox"/>	Hypertrophic Obstructive Cardiomyopathy

	Patent ductus arteriosus
	Fallot's tetralogy

□ Question 110 of 193

A 78-year-old man is admitted with palpitations and shortness of breath. He denies chest pain apart from mild angina on exertion. He can't quite recall when the symptoms started but he felt normal a week ago. He is sent to the medial admissions unit for serial troponins but an ECG on arrival shows no ischaemic changes.

His background includes hypertension, atrial fibrillation, recurrent transient ischaemic attacks, and moderate left ventricular systolic dysfunction. He takes carvedilol, dabigatran and digoxin daily. In addition the patient's GP has recently doubled the daily dose of furosemide.

The ward nursing staff ask you to review the patient as he says the palpitations have suddenly become much worse. His blood pressure is stable.

Na ⁺	140 mmol/l
K ⁺	3.2 mmol/l
Urea	9.9 mmol/l
Creatinine	188 mol/l

A repeat ECG shows monomorphic ventricular tachycardia. The on-call cardiologist agrees that this patient should receive digibind. However the nursing staff tell you that digibind will take 30 minutes to arrive on the ward.

What in the next step in this patient's management?

	DC cardioversion
	IV Metoprolol
	IV Atropine
	IV Phenytoin
	Proceed to PCI

□ Question 111 of 193

□ □

An 85-year-old man is reviewed in cardiology clinic as part of the ongoing assessment for possible intervention for severe aortic stenosis. The patient had been under surveillance for aortic valve disease over the previous 10 years and a progressive worsening of aortic valve function had been documented. However, the patient had remained asymptomatic until the onset of pre-syncope symptoms on exertion around 6 months previously. At that time, the patient had expressed interest in undergoing either surgical aortic valve replacement or transcatheter aortic valve insertion if recommended by his doctors. Subsequently, the patient had undergone a variety of investigations to assess the risk associated with the above procedures.

The patient was in good general health and lived independently in a bungalow with his wife. He had no other history of cardiac disease. The patient had been diagnosed with type 2 diabetes mellitus 10 years previously, which was well controlled on oral metformin and a daily long-acting insulin injection. He also took ramipril as the treatment for hypertension and chronic kidney disease. The patient was a lifetime non-smoker and rarely consumed alcohol.

A summary of the investigations undergone by the patient is given below.

Haemoglobin	145 g / dL
Mean cell volume	89.1 fL
White cell count	4.3 x 10 ⁹ / microlitre
Platelets	198 x 10 ⁹ / microlitre
Urea	7.8 mmol / L
Creatinine	133 micromol / L
Sodium	143 mmol / L
Potassium	3.9 mmol / L

Investigation	Result
Transthoracic echocardiogram	Severe aortic stenosis (valve area 0.9 cm ²); no other valve disease; normal systolic function

Coronary angiography	Minor irregularities only; no flow-limiting stenosis
Iliofemoral angiography	No significant atherosclerosis
Pulmonary function tests	No evidence significant obstructive or restrictive lung disease

Following the above assessment, surgical aortic valve replacement was estimated to carry a 4.0 % risk of mortality and 1.9 % risk of permanent stroke (intermediate risk). No contraindications to transfemoral or transapical transcatheter aortic valve insertion were identified.

What is the recommended choice of intervention for the patient's aortic stenosis?

<input type="checkbox"/>	Transfemoral transcatheter aortic valve insertion
<input type="checkbox"/>	Transapical transcatheter aortic valve insertion
<input type="checkbox"/>	Surgical aortic valve replacement and transcatheter aortic valve insertion inappropriate
<input type="checkbox"/>	Surgical aortic valve replacement with mechanical valve

Question 114 of 193

□ □

A 83 year old lady presents to heart failure follow up clinic. She has a history of NSTEMI and gallstones. Her symptoms are reasonably poorly controlled. She is able to walk around her bungalow, but struggles to walk to her local shops 100m away due to breathlessness.

She had recently seen her GP who added spironolactone to her regular medications due to persistent hypokalaemia. Her potassium has since normalised.

Her latest echo reveals an ejection fraction of 25%. Her ECG is sinus rhythm Her last BNP was 1000 pg/ml.

She is currently taking senna, ramipril 10mg, aspirin 75m, frusemide 40mg bd, simvastatin 40mg, and spironolactone 50mg.

Her observations at clinic are:

- oxygen saturations: 94% on room air
- blood pressure: 126/66 mmHg
- heart rate: 84/min

Which additional medication would be beneficial?

	Ivabradine
	Bisoprolol
	Digoxin
	Diltiazem
	Atenolol

Question 115 of 193

□ □

Mr Smith is a 59-year-old man who presents to the walk-in clinic complaining of central chest pain that is sharp in nature and is associated with a low-grade fever of 37.9°C. He complains that it is worse when he goes to bed at night and better when he sits forward. He denies any recent infections or trauma to the chest. Upon reading the patient's notes the following entry is found dated 2 weeks previously. It reads as follows:

Mr Smith presented to the emergency department with central crushing chest pain that radiated to his jaw that started 40 minutes ago. The admitting ECG revealed marked ST-elevations in leads II, III, and AVF. He was sent directly for percutaneous coronary intervention where a stent was inserted into the right coronary artery...

Given the history and the current presenting complaint, what is the most likely diagnosis?

	Ventricular free wall rupture
	Myocardial infarction
	Dressler's syndrome
	Viral pericarditis
	Pneumonia

□ Question 117 of 193

A 73-year-old man with a history of severe biventricular heart failure comes to the clinic for review. He can only walk around 100 metres to the bus stop and climbs the stairs once per day only. Medication includes ramipril 10mg, furosemide 80mg, bisoprolol 10mg, spironolactone 25mg, aspirin and atorvastatin. On examination his blood pressure is 123/82 mmHg, pulse is 85 beats per minute at rest. He has bilateral basal crackles on auscultation of the chest and mild pitting oedema of both ankles.

Investigations

Hb	122 g/l	Na ⁺	134 mmol/l	Bilirubin	11 µmol/l
Platelets	190 * 10 ⁹ /l	K ⁺	5.0 mmol/l	ALP	105 u/l
WBC	7.4 * 10 ⁹ /l	Urea	11.2 mmol/l	ALT	33 u/l
Neuts	4.5 * 10 ⁹ /l	Creatinine	142 µmol/l	γGT	56 u/l
Lymphs	1.2 * 10 ⁹ /l			Albumin	38 g/l
Eosin	0.5 * 10 ⁹ /l				

Chest x-ray: Cardiomegaly, bilateral upper lobe diversion

ECG: Left bundle branch block, ventricular rate 85

ECHO: Ejection fraction 31%

Which of the following is the most appropriate next step with regards to his heart failure medication?

	Add digoxin
	Add valsartan
	Add ivabradine

	Increase furosemide by 40mg per day
	Increase spironolactone to 100mg per day

Dashboard

□ Question 118 of 193

A 37-year-old gentleman is referred to the cardiology clinic with a 7-month history of bilateral foot pain. Initially, the pain only occurred towards the end of his daily commute; improving when he sat at his desk, but over the past 3 weeks his symptoms have progressed. The pain is now provoked by walking short distances and has occasionally occurred at rest. He describes being woken by the pain at night, although he is able to obtain relief by standing on the cool tiles in his bathroom. He eventually decided to see his GP when he developed similar pain in his right wrist 10 days ago.

His past medical history is unremarkable. There is no history of hypertension, dyslipidaemia or diabetes. He is a current smoker with a 20 pack year history. He drinks alcohol in moderation.

On examination, both feet are noted to be smooth and hairless. The right dorsalis pedis is difficult to feel and the medial 3 toes are cold and dusky. Urgent angiography is performed and shows a number of distal stenoses in the right limb affecting the anterior and posterior tibial arteries as well as the distal fibular artery. A number of similar stenoses are seen in the contralateral limb with 'corkscrew' collateral formation.

Blood tests are as follows:

Hb	130 g/l	Na ⁺	139 mmol/l
Platelets	322*10 ⁹ /l	K ⁺	4.1 mmol/l
WBC	9.1*10 ⁹ /l	Urea	5.3 mmol/l
Neuts	6.2*10 ⁹ /l	Creatinine	113 µmol/l
Lymphs	2.1*10 ⁹ /l	CRP	19 mg/l
Eosin	0.1*10 ⁹ /l		

MPO	negative
PR3	negative
anti-cardiolipin	negative

What is the most likely diagnosis?

	Peripheral vascular disease
	Microscopic polyangiitis
	Takayasu arteritis
	Thromboangiitis obliterans
	Polyarteritis nodosa

□ Question 119 of 193

□ □

A medical opinion was sought from the obstetrics team regarding a 38-year-old 28 weeks pregnant lady. A routine blood pressure check revealed a blood pressure of 158/98 mmHg. Other than suffering from hyperemesis gravidarum, her pregnancy had proceeded without complication. She specifically denied the presence of headaches, vomiting, change in vision, abdominal pain, seizures or bleeding per vagina. She had noticed no change in the frequency of foetal movements, and her 20-week antenatal scan revealed the presence of a healthy foetus with a rate of growth within the expected range. Her past medical history was unremarkable; she was a non-smoker and did not consume alcohol. Her blood pressure at the booking antenatal appointment was 148/88 mmHg. Her sister suffered from pre-eclampsia during her pregnancy necessitating delivery by caesarean section.

Examination revealed the presence of a well 28-week old pregnant lady. Her blood pressure was indeed 158/98 mmHg, her heart rate was 86 bpm and temperature 36.5°C. Examination of the cardiovascular system revealed normal heart sounds, a JVP of 3cm and the absence of pedal oedema. Examination of the respiratory system was unremarkable. Examination of the gastrointestinal system revealed the presence of a symphysiofundal height appropriate for the stage of gestation with easily obtainable foetal heart sounds on hand held Doppler examination. Examination of the neurological system was unremarkable with normal reflexes, cranial nerve function and peripheral motor and sensory function. Urinalysis revealed no abnormality.

What is the next best management step?

	Commence ramipril
	Commence labetalol
	Commence indapamide
	Commence magnesium sulphate
	Transfer to high dependency unit to observe for signs of pre eclampsia

Overall score: **0%**

Question 120 of 193

A 56-year-old man is brought to the Emergency Department. He works as a window cleaner. His colleague describes him suddenly falling from the ladder without warning. On admission he is conscious with a bradycardia of around 36/min. His blood pressure is 110/62 mmHg and he is well perfused with no signs of heart failure. An ECG is taken on account of his bradycardia:

© Image used on license from Dr Smith, University of Minnesota

A previous ECG taken four months ago was completely normal. What is the most likely diagnosis?

	Sick sinus syndrome
	Stokes-Adams attack with associated complete heart block
	Myocardial infarction with new left bundle branch block
	Second-degree atrioventricular block (Mobitz II)
	Second-degree atrioventricular block (Mobitz I / Wenckebach)

Overall score: **0%**

□ Question 121 of 193

A 58-year-old woman was admitted with a stroke following a month's history of recurrent fevers, anorexia and weight loss. On examination, she had a left-sided hemiparesis and facial droop. Cardiovascular examination revealed splinter haemorrhages in 5 of her fingers across both hands, and a soft diastolic murmur heard loudest in expiration over the aortic area.

A trans-thoracic echocardiogram showed an oscillating vegetation on an aortic leaflet, in the path of regurgitant jets. Two blood cultures were positive for *Streptococci* spp. She was diagnosed with infective endocarditis and started on intravenous benzylpenicillin 1.2g every 4 hours and gentamicin 1mg/kg twice daily therapy.

She was reviewed after 5 days on antibiotic therapy with the following results.

Na ⁺	139 mmol/l
K ⁺	4.7 mmol/l
Urea	14.2 mmol/l
Creatinine	178 µmol/l
Serum bilirubin	16 µmol/l
Serum alkaline phosphatase	115 IU/l
Serum aspartate aminotransferase	18 IU/l
C Reactive protein	89 mg/l
Haemoglobin	138 g/l
White cell count	13.6 x 10 ⁹ /L
INR	1.1
Blood cultures	<i>Streptococcus Bovis</i>
Penicillin Minimum Inhibitory Concentration (MIC)	0.6 mg/L (high)
ECG	Prolonged PR interval (not present on admission ECG)

What is the next most important management?

	Increase antibiotics to intravenous benzylpenicillin 2.4g every 4 hours and gentamicin 1mg/kg twice daily
	Organise an urgent colonoscopy
	Switch antibiotics to ceftriaxone 2g once daily
	Refer to cardiothoracic surgeons
	Organise urgent trans-oesophageal echocardiogram

Question 122 of 193

A 58 year-old man with a background of ischaemic heart disease and Crohn's disease has developed colonic enterocutaneous fistulae. He is admitted to hospital under the surgical team and a temporary ileostomy is formed to defunction the bowel and promote healing.

Two days post-operatively he develops palpitations and the surgical team request your assistance.

On examination the pulse rate is 220bpm and the blood pressure is 135/90mmHg. Oxygen saturations are 96% on 2L nasal oxygen.

The chest is clear to auscultation.

A 12-lead ECG reveals a wide-complex tachycardia with a polymorphic waveform.

Blood tests from the morning reveal:

Hb	129 g/l
Platelets	643 * 10 ⁹ /l
WBC	13.8 * 10 ⁹ /l
Na ⁺	129 mmol/l
K ⁺	3.3 mmol/l
Phosphate	0.63 mmol/l
Mg ⁺⁺	0.59 mmol/l
Urea	8.1 mmol/l
Creatinine	97 µmol/l
Bilirubin	15 µmol/l
ALP	143 u/l
ALT	53 u/l

Albumin	31 g/l
---------	--------

What is the most appropriate initial management?

	Adenosine 6mg IV
	Magnesium sulphate 2g
	Metoprolol 5mg IV
	Synchronised DC shock
	Amiodarone 300mg IV

Question 123 of 193

□ □

A 48-year-old man is brought in by ambulance to the Emergency Department after experiencing sudden onset crushing central chest pain radiating down his arm. His ECG showed an inferior STEMI and he undergoes successful PCI with 2 stents inserted into his right coronary artery. He is transferred to CCU and started on secondary prevention medication.

24 hours after his presentation he becomes bradycardic at 34bpm and his blood pressure falls to 80/47 mmHg. He denies chest pain but feels dizzy and light headed. His cardiac monitor shows 3rd-degree heart block. He is given atropine but his heart rate does not raise and his blood pressure remains low.

What is the most appropriate next step in his management?

	Isoprenaline infusion
	Temporary pacing wire
	Permanent pacemaker
	Repeat angiography
	Adrenaline

□ □

You are working in the general medical clinic where a 42 year old woman comes for review following a recent, short admission to hospital where she was treated for a paracetamol overdose. She has a past history of depression but denies any other previous problems.

During the review, she is found to have a manual blood pressure reading of 165/85 mmHg. Clinical examination of cardiovascular and respiratory systems are normal, as is urine dip and fundoscopy. Given this information what should be your next course of management in relation to her blood pressure.

	Start ramipril
	Offer ambulatory blood pressure monitoring
	Arrange to check blood pressure again following a two week interval
	Start amlodipine
	Screen for causes of secondary hypertension

□ Question 125 of 193

□ □

Whilst covering medical receiving over night, you are referred a 52 year old man presenting to the Emergency Department with palpitations. He describes 'fluttering in the chest' for the last 48 hours. His past medical history is remarkable only for type 1 diabetes, adequately controlled with insulin. His admission ECG shows atrial fibrillation with a ventricular rate of 130-140 beats per minute. Examination reveals; blood pressure 88/60 mmHg, with capillary refill 3 seconds. His chest is clear to auscultation. He scores 15/15 on the Glasgow coma score. The patient feels light headed but is otherwise uncomplaining. What is the next, best course of management:

	Monitor and observe the patient on the Coronary Care Unit
	Load with 300mg, intravenous amiodarone
	Attempt vagal manoeuvres
	Give 5mg intravenous metoprolol as a slow bolus
	Arrange DC cardioversion

Question 130 of 193

□ □

A 35-year-old Sri-Lankan lady is referred to the medical registrar by the obstetric registrar with hypoxia. She had just undergone an emergency caesarean section and had had to be transfused with four units of blood and intravenous fluids because of post-partum haemorrhage. She was otherwise fit and well and was taking no regular medications. It was her first pregnancy and she had had no problems other than a prolonged labour. There was no history of orthopnoea, chest pain or exertional dyspnoea. On examination she has widespread fine crepitations throughout both lung fields and a soft systolic and a soft diastolic murmur. Her respiratory rate is 24 breaths per minute and her oxygen saturations are 94% breathing 40% oxygen. Her heart rate is 105 beats per minutes and blood pressure 149/78 mmHg. A chest x-ray reveals features of acute pulmonary oedema with no cardiomegaly.

What is the most likely underlying diagnosis?

	Transfusion related acute lung injury (TRALI)
	Mitral stenosis
	Pulmonary embolus
	Peri-partum cardiomyopathy
	Basal atelectasis

Question 131 of 193

□ □

A 74-year-old woman is reviewed prior to discharge from a care of the elderly ward. She was admitted with urosepsis and found to have atrial fibrillations as well. She was treated over five days with first IV antibiotics and then oral antibiotics.

Her temperature has settled her symptoms have resolved. Her heart rate is now regular and within normal range. This occurred over the first 24hrs of admission as her sepsis was treated. She has a background of osteoarthritis, osteoporosis, hip fracture, glaucoma, hypothyroidism, hypertension and congestive cardiac failure. She takes alendronic acid, cholecalciferol, levothyroxine, amlodipine and ramipril. How should the episode of AF be managed in terms of anticoagulation?

	No further management needed
	Monitor with Holter monitor over 48hrs
	Clinical review in six weeks
	Offer anticoagulation with aspirin
	Offer anticoagulation with warfarin or NOAC

Dashboard

Question 132 of 193

□ □

A 78-year-old woman presents to the emergency department with complaints of palpitations. Her episodes of palpitations occur roughly once a month and are not associated with any chest pain or shortness of breath. She has a past medical history of ischaemic heart disease, type 2 diabetes, depression, hypertension and migraines. She takes aspirin, metformin, simvastatin and uses paracetamol when she needs them for headaches. She lives alone with a twice daily package of care.

An ECG demonstrates an irregularly irregular rhythm with no p-waves. She is offered bisoprolol to control her symptoms but does not want to take it regularly. She asks if she could take the bisoprolol only when she has palpitations as they occur so rarely. What would make a 'pill-in-the-pocket' strategy inappropriate for her?

	Hypertension
	History of ischaemic heart disease
	Age
	Living alone
	Palpitations too frequent

Dashboard

□ Question 133 of 193

A 78-year-old woman attends the cardiology outpatient department after being referred by her general practitioner with angina. The patient reports consistent chest tightness after walking around 200 metres on flat ground but denies any episodes of pain at rest. Her symptoms have been stable at the current level for at least six months. Her GP has previously attempted treatment with both metoprolol and amlodipine but both were stopped after the patient reported dizziness and was found to be hypotensive.

The patient was formerly a heavy smoker but had stopped 15 years previously after suffering a non-ST elevation myocardial infarction (managed with medical therapy only). The patient had been diagnosed with type 2 diabetes mellitus 10 years previously and was known to have chronic kidney disease.

The patients current medications included aspirin 75 mg daily, simvastatin 20 mg daily, ramipril 1.25 mg daily and gliclazide 60 mg twice daily. She sometimes used a nitrate spray to relieve episodes of angina but found that it normally made her very dizzy.

Clinical examination was unremarkable except for a blood pressure of 98 / 65 mmHg.

Please see below for results of recent investigations.

Transthoracic echocardiogram: normal valvular function; moderately impaired left ventricular; ejection fraction 35 %.

Electrocardiogram: sinus rhythm at 85 beats per minute; normal axis; normal QRS complex, normal ST segments and T waves.

Urea	15.6 mmol / L
Creatinine	234 micromol / L
Sodium	135 mmol / L
Potassium	4.9 mmol / L

Cardiac stress MRI: evidence of mild myocardial ischaemia in left anterior descending territory, estimated < 10 % myocardium ischaemic.

What is the correct next line therapy for the patients angina?

	Percutaneous coronary intervention
	Nicorandil
	Ranolazine
	Ivabradine
	Long-acting isosorbide mononitrate

Dashboard

Question 134 of 193

□ □

A 56-year-old gentleman was admitted to the Emergency Department with a three-hour history of severe central chest pain. The pain came on suddenly whilst he was walking. The pain has remained severe in intensity since onset. He also felt short of breath at rest with associated clamminess. There was no history of trauma. His past medical history comprised of hypertension, hypercholesterolaemia and gout. He was prescribed amlodipine 5mg OD, ramipril 7.5mg OD, atorvastatin 20mg OD, allopurinol 100mg and orlistat 120mg TDS. He smoked 20 cigarettes per day and consumed 30 units of alcohol per week.

On examination, he appeared pale and clammy. His blood pressure was 196/78 mmHg in his right arm and 152/65 mmHg in his left arm. His heart rate was 92bpm. His oxygen saturations were 96% on air. Examination of his cardiovascular system revealed the presence of a prominent early diastolic murmur in the aortic area. Examination of his respiratory system revealed tachypnoea but no added sounds on auscultation. Examination of his gastrointestinal and neurological systems was unremarkable.

He was admitted to the resuscitation bay and commenced on 15 litres of oxygen per minute. He was administered IV diamorphine 2.5mg OD. Investigations conducted revealed the following results:

ECG: normal sinus rhythm 96 bpm, ST elevation in leads II, III and aVF

Chest x-ray: normal appearances of heart and lung

What is the best immediate management step?

	Commence thrombolysis
	Transfer for immediate percutaneous coronary intervention
	Commence aspirin 300mg OD and clopidogrel 300mg OD
	Conduct myocardial perfusion scan
	Commence IV labetalol infusion

Overall score: **0%**

□ Question 135 of 193

A 73 year old man was admitted as an emergency suffering from severe, central and crushing chest pain. ECG revealed evidence of anterior ST elevation MI and primary percutaneous coronary intervention was performed with deployment of two drug-eluting stents to the left anterior descending artery. The patient had no previous coronary artery disease or significant family history. He is an ex-smoker and drinks approximately 10 units of alcohol per week.

Post-procedure the patient was well and mobilised on the ward without further chest pain or shortness of breath. Clinical examination was unremarkable.

The patient was commenced on aspirin, clopidogrel, ramipril, bisoprolol and atorvastatin therapy. Further investigations performed following intervention are summarised as below.

Haemoglobin	13.9 d / dL
White cell count	$8.6 \times 10^9/l$
Platelets	$199 \times 10^9/l$
Urea	7.2 mmol / L
Creatinine	110 micromol / L
Sodium	137 mmol / L
Potassium	4.3 mmol / L
Total cholesterol	5.4 mmol / L
LDL cholesterol	3.1 mmol / L
HDL cholesterol	1.2 mmol / L
Triglycerides	2.5 mmol / L

Transthoracic echocardiogram: no valvular abnormality; mild anterior dyskinesia with overall normal left ventricular systolic function; ejection fraction 55-60 %

Primary PCI report: total occlusion of mid-LAD, two DES deployed with good angiographic result; 50 % mid-vessel

occlusion of right coronary artery; circumflex unobstructed.

Prior to discharge the patient asks to speak to you about any other possible strategies to reduce his risk of suffering a further heart attack.

Which of the following interventions is recommended for this patient by NICE guidance on secondary prevention of myocardial infarction?

	Percutaneous coronary intervention to right coronary artery
	Mediterranean-style diet
	Abstinence from alcohol
	Omega-3 fatty acid supplements
	Aldosterone antagonist (for example, eplerenone)

Question 136 of 193

A 64-year-old male presents sudden onset back pain while painting a wall at home, radiating to his left anterior chest and jaw, associated with nausea and vomiting. It appears to be constant for the past 3 hours since onset and is his first ever episode. His past medical history includes hypertension, hypercholesterolaemia and one previous transient ischaemic attack.

His ECG demonstrates left ventricular hypertrophy by voltage criteria and T-wave inversion in I, aVF and V5 and V6. On examination, his heart sounds are both present with a soft systolic murmur. The chest is clear and abdomen is soft and non-tender without a pulsatile mass. Both radial pulses are intact with no delay. There is a mild radio-femoral delay. His blood pressure is stable at 134/80 mmHg, heart rate 124/min and sinus rhythm. His bloods are as follows:

Hb	123 g/l
MCV	82 fl
Platelets	204 * 10 ⁹ /l
WBC	9.2 * 10 ⁹ /l
Troponin T	240 (normal range < 32)

His pain settles transiently with 2.5mg of subcutaneous morphine. What is the most appropriate immediate action?

	Aspirin 300mg and clopidogrel 300mg and treatment dose low molecular weight heparin
	Intravenous fluids
	Blood transfusion
	Coronary angiogram +/- stent as appropriate
	CT aorta

Overall score: **0%**

Question 137 of 193

A 50-year-old woman is seen by her GP for a routine check-up. She has a past medical history of congestive cardiac failure secondary to hypertension. She takes lisinopril, bisoprolol, simvastatin and aspirin. Her symptoms are largely controlled, but her blood pressure is 140/95mmHg.

On examination, she appears well. She is overweight, but independently mobile. Her heart rate is 80 beats per minute. She has a few scattered crepitations on chest auscultation, but no wheeze. She is afebrile, with pitting oedema to the ankles.

Bloods show:

Hb	14.2 g/dl
Platelets	215 * 10 ⁹ /l
WBC	7.5 * 10 ⁹ /l

Na ⁺	140 mmol/l
K ⁺	4.8 mmol/l
Urea	4 mmol/l
Creatinine	75 µmol/l
Fasting blood glucose	5.3 mmol/L

What is the most appropriate option for this lady?

	No further treatment
	Amlodipine
	Indapamide

	Candesartan
	Increase dose of lisinopril

□ Question 137 of 193

□ □

A 50-year-old woman is seen by her GP for a routine check-up. She has a past medical history of congestive cardiac failure secondary to hypertension. She takes lisinopril, bisoprolol, simvastatin and aspirin. Her symptoms are largely controlled, but her blood pressure is 140/95mmHg.

On examination, she appears well. She is overweight, but independently mobile. Her heart rate is 80 beats per minute. She has a few scattered crepitations on chest auscultation, but no wheeze. She is afebrile, with pitting oedema to the ankles.

Bloods show:

Hb	14.2 g/dl
Platelets	215 * 10 ⁹ /l
WBC	7.5 * 10 ⁹ /l

Na ⁺	140 mmol/l
K ⁺	4.8 mmol/l
Urea	4 mmol/l
Creatinine	75 µmol/l
Fasting blood glucose	5.3 mmol/L

What is the most appropriate option for this lady?

	No further treatment
	Amlodipine
	Indapamide
	Candesartan

Key

A = ACE inhibitor

C = Calcium channel blocker

D = Thiazide Diuretic

Question 138 of 193

□ □

A 69-year-old gentleman is reviewed in cardiology clinic. He has been suffering from angina for five years and despite optimal medical management he finds that his symptoms are worsening. He has a past medical history of type 2 diabetes mellitus, gout and hypertension. He is currently taking felodipine, atenolol, atorvastatin, aspirin, ramipril and metformin. He has recently undergone an angiogram which has delineated triple vessel disease. He is very keen to optimise his survival chances as he is concerned about dying of a heart attack.

What intervention would have the greatest survival advantage?

	Aggressive control of blood pressure, cholesterol and diabetes
	Percutaneous coronary intervention (PCI) with insertion of stents
	Coronary arterial bypass graft (CABG)
	No intervention will give a further survival advantage
	Heart transplant

□ Question 139 of 193

A 45 year old female presents with a two month history of reduced appetite and one and half stone of weight loss in the past two months. She reports no pain but has noted an abdomen to be increasingly distended, which she notes to be uncomfortable and impairing her breathing. She has no other past medical history, is a non-smoker and does not drink alcohol to excess. Her mother and aunt both passed away in their 50s and 60s respectively from ovarian cancer. When you examine her, you note abdominal distension and tenderness on deep palpation. Her flanks appear dull to percussion with percussion splash on auscultation. Examinations of her respiratory, cardiovascular and neurological systems are unremarkable. An admission chest radiograph demonstrates clear lung fields. Her initial blood results are as follows:

Hb	14.1 g/dl
Platelets	304 * 10 ⁹ /l
WBC	9.0 * 10 ⁹ /l
Na ⁺	133 mmol/l
K ⁺	4.2 mmol/l
Urea	7.8 mmol/l
Creatinine	125 µmol/l
CRP	80 mg/l
Tumour markers	Not yet reported

A CT of her chest, abdomen and pelvis with contrast reveals moderate amounts of ascites associated with contrast enhancing lesions on various sites of her peritoneum. No lymphadenopathy or masses are detected.

Her tumour markers return as below:

Ca 125	280
(normal <35units/ml)	
Ca 19-9	12 (normal range <37 units/ml)

Ca 15-3	12 (normal <30 units/ml)
CEA	3.4 (normal range < 5.5ng/ml)
Alpha 1 fetoprotein	88 (normal range < 400ng/ml)

What is the appropriate next management?

	Start platinum-based chemotherapy for epithelial ovarian carcinoma
	Start platinum-based empirical chemotherapy for breast carcinoma
	Ascitic drain with human albumin solution, send for serum-ascites albumin gradient, MCS, cytology
	Ascitic drain without human albumin solution, send for serum-ascites albumin gradient, MCS, cytology
	Repeat tumour markers in 6 weeks

Dashboard

Question 140 of 193

A 30-year-old man presents with a fever. He complains that he has had a fever, headache and lethargy for three weeks. On examination, his temperature is 38.5C. You notice a healed human bite mark on his right forearm, he tells you he was bitten in a pub brawl about a couple months ago. Diastolic and systolic murmurs are heard on auscultation. A trans-oesophageal echo demonstrates an oscillating mass on a bicuspid aortic valve, with aortic regurgitation. Three blood cultures are taken before administration of empirical antibiotics, two grow small colonies of tiny pleomorphic gram-negative bacilli.

What is the likely causative organism?

	<i>Eikenella corrodens</i>
	<i>Escherichia coli</i>
	<i>Phoenicoparrus andinus</i>
	<i>Staphylococcus aureus</i>
	<i>Streptococcus viridans</i>

Question 143 of 193

A 45-year-old woman develops severe central chest pain. An ECG in the ambulance shows ST segment elevation in leads: I, aVL, V2-6. Shortly after she arrives in hospital the pain resolves and a second ECG is entirely normal. She has had three similar episodes of chest pain in the past. All episodes of chest pain have come on at rest. Blood pressure is 140/80 mmHg, heart rate is 90 beats per minute and hearts sounds are normal. She underwent coronary angiography following a previous episode of chest pain three weeks ago, which showed no significant coronary artery disease. An echocardiogram is normal.

What is the likely diagnosis?

	Acute anterolateral myocardial infarction
	Crescendo angina
	Da Costas syndrome
	Prinzmetal's variant angina
	Takotsubo cardiomyopathy

□ Question 144 of 193

A 52-year-old man of Afro-Caribbean descent is reviewed after having ambulatory blood pressure monitoring (ABPM). This had been ordered after a works medical recorded a blood pressure of 156/86 mmHg. He smokes 20 cigarettes/day and has a family history of ischaemic heart disease. The results show the following:

Average daytime blood pressure: 142/88 mmHg

QRISK 10 year cardiovascular risk: 23%

Urine dipstick: NAD

ECG: sinus rhythm, rate 78/min

Na ⁺	141 mmol/l
K ⁺	4.6 mmol/l
Urea	4.5 mmol/l
Creatinine	82 µmol/l
Total cholesterol	5.4 mmol/l
HDL cholesterol	0.9 mmol/l
Fasting glucose	5.3 mmol/l

What is the most appropriate course of action?

<input type="checkbox"/>	Start treatment with a calcium channel blocker
<input type="checkbox"/>	Diagnose stage 1 hypertension and advise about lifestyle changes
<input type="checkbox"/>	Start treatment with an ACE inhibitor

Question 145 of 193

□ □

A 50-year-old patient with no prior medical history presents to the Emergency Department with crushing central chest pain. On examination you find:

- Respiratory rate - 22/min
- Oxygen saturations 95% on room air
- Chest clear
- Pulse 118bpm
- Blood pressure 92/61mmHg
- JVP elevated 4cm above sternal angle

An ECG done in the department shows 3mm ST segment elevation in leads II, III and aVF. The patient undergoes a primary PCI to his right coronary artery with a good angiographic result. An echocardiogram is performed the following day. What would you expect to see?

	Regional wall motion abnormality in the inferior wall of the LV
	Regional wall motion abnormality in the inferior wall of the LV with a dilated and impaired RV
	Normal biventricular function
	Constrictive pericarditis
	Regional wall motion abnormality in the inferior wall of the LV with mitral regurgitation

□ Question 146 of 193

An 84-year-old man comes for review. Four weeks ago an opportunistic blood pressure reading was taken and recorded as 150/92 mmHg. You therefore arranged ambulatory blood pressure monitoring (ABPM) along with a standard hypertension work-up. You did not calculate his 10-year cardiovascular risk on account of his age. The following results were obtained:

Na ⁺	141 mmol/l
K ⁺	4.2 mmol/l
Urea	6.5 mmol/l
Creatinine	101 µmol/l
Total cholesterol	4.9 mmol/l
HDL cholesterol	1.2 mmol/l
Fasting glucose	5.5 mmol/l

Urine dipstick was normal. The ECG showed sinus rhythm, 72 bpm and first degree heart block.

The daytime average blood pressure reading was 145/80 mmHg. What is the most appropriate course of action?

	Diagnose stage 1 hypertension and advise about lifestyle changes
	Start treatment with an ACE inhibitor
	Start treatment with a calcium channel blocker
	Start treatment with a thiazide-like diuretic
	Repeat the ABPM

Question 147 of 193

□ □

A 79 year old male presents with two months history of reducing exercise tolerance and increasing lower limb oedema. He is now short of breath on minimal exertion, greatly restricts his ability to perform activities of daily living. He is on maximum doses of ramipril, bisoprolol, 80mg furosemide and spironolactone. His last ejection fraction 3 months ago was 30%. His ECG demonstrates no acute ischaemic changes, with a left bundle branch block (old confirmed with previous ECG from 4 months ago), sinus rhythm and QRS complex width of 170ms. What is the next optimal treatment?

	Increasing furosemide to 80mg BD
	Addition of eplerenone
	Addition of ivabradine
	Cardiac resynchronisation therapy (CRT)
	Cardiac resynchronisation therapy (CRT) and implantable cardiac defibrillator (ICD) insertion

Question 150 of 193

A 60-year-old patient is called to his GP for a health check. He has a past medical history of asthma and a family history of hypertension and bowel cancer. He has a 10 pack-year history of smoking but quit with the help of the practice nurse 2 years ago. He drinks 24 units of alcohol per week, and his body mass index is 25 kg/m². He does not take any regular medication. His blood pressure is 155/95 mmHg. He is sent for ambulatory blood pressure monitoring (ABPM), which shows an average blood pressure of 145/90 mmHg. His 10-year cardiovascular risk is 12%.

Examination, including fundoscopy, is unremarkable.

Bloods show:

Hb	132 g/l
Platelets	330 * 10 ⁹ /l
WBC	7.3 * 10 ⁹ /l

Na ⁺	142 mmol/l
K ⁺	3.9 mmol/l
Urea	5 mmol/l
Creatinine	80 µmol/l
eGFR	91 ml/min
Fasting plasma glucose	5mmol/L
Serum total cholesterol	4mmol/L
HDL cholesterol	1.8mmol/L

Urinary albumin:creatinine ratio	1.1 mg/mmol
Urine dip	negative for haematuria

An ECG shows sinus rhythm.

What is the first step in the management of this man's blood pressure?

	Lisinopril
	Lifestyle advice
	Amlodipine
	Spironolactone
	Atenolol

Question 151 of 193

□ □

A 66-year-old Caucasian female presents with 3 week history of worsening headache and 2 day history of shortness of breath. She reports disturbed sleeping at night due to an inability to lie down, due to her shortness of breath. She has no known past medical history and drug history. On examination, you note bilateral splinter haemorrhages, 4 on the right and 2 on the left, with calcium deposits distally and black spots in the pulp of the fingers. Perioral skin puckering is also noted. Cardiovascular examination is unremarkable, chest examination reveals bilateral coarse inspiratory crackles. Neurological examination is unremarkable except fundoscopy revealing papilloedema, cotton wool spots and flame haemorrhages. The patient is afebrile, Sats 95% on 2 litres, respiratory rate 24/min, blood pressure 195/115 mmHg, HR 90/min and regular. Chest x-ray demonstrates bilateral pleural effusion with bilateral alveolar shadowing. What is the most important immediate management?

	Oral amlodipine
	Oral captopril
	Intravenous labetalol
	Oral high-dose prednisolone
	Renal dialysis

□ Question 152 of 193

□ □

An 80-year-old woman presents with dyspnoea to the Emergency Department. According to her daughter she has been getting progressively worse over the past 4 weeks. Her past medical history includes a myocardial infarction 20 years ago following which she had a 'pacemaker' inserted. She still smokes 20 cigarettes/day.

On examination her pulse is 120/min irregularly irregular. Blood pressure is 102/72 mmHg, oxygen saturations are 94% on 40% oxygen via a Venturi mask.

Her chest x-ray is shown below:

© Image used on license from Radiopaedia

What is the most appropriate initial treatment?

	Oral beta-blocker
	Low-molecular weight heparin
	Intravenous loop diuretic
	Reduce oxygen to 24% and nebulised bronchodilator
	Intravenous broad-spectrum antibiotic

Dashboard

Overall score: 0%

Question 153 of 193

You are asked to review a 22-year-old female with a heart murmur. Her height is 4ft 7 inches and she reports having always been short for her year. She has been diagnosed with autoimmune hypothyroidism, for which she is taking levothyroxine replacement and is also taking 'hormone replacement to protect her bones' after her GP noted she had not started her periods by 19 years old.

On examination, you note short 4th metacarpals on both hands and lymphoedematous in her hands and feet. Auscultation of her precordium reveals an ejection systolic murmur at the left infraclavicular region. Her body mass index is 22.4 kg/m². The patient's blood tests are as follows:

Hb	123 g/l
Platelets	380 * 10 ⁹ /l
WBC	6.5 * 10 ⁹ /l

Na ⁺	144 mmol/l
K ⁺	4.8 mmol/l
Urea	7.2 mmol/l
Creatinine	110 µmol/l
Adjusted calcium	2.40 mmol/l
Phosphate	1.1 mmol/l
PTH	9 mg/dl (8.5-10.2mg/dl)

What is the underlying unifying diagnosis?

	Turner's syndrome
	Pseudohypoparathyroidism

	Pseudopseudohypoparathyroidism
	Noonan syndrome
	Down's syndrome

Question 154 of 193

□ □

A 60-year-old woman has a heart rate of 180bpm on the medical admission unit. An ECG performed demonstrates a regular narrow-complex tachycardia. The patient complains of palpitations but no chest pain and blood pressure remains 140/95. Initial vagal maneuvers are performed including carotid massage with no success. Intravenous adenosine 6mg is given followed by a further two doses of adenosine 12mg. Unfortunately, this failed to cardiovert or reveal an interpretable underlying rhythm.

What is the next management step?

	Further adenosine
	Synchronised DC cardioversion
	Verapamil
	Digoxin
	Amiodarone

Dashboard

□ Question 155 of 193

A 34 year old man attended the Emergency Department after experiencing a severe sudden onset headache at home. The pain was felt across the whole of the head and reached a 10/10 severity within a few seconds of onset. Since the headache began the patient had experienced a loud pulsatile pounding noise in his right ear. There was no reported loss of consciousness or other neurological symptoms. In the preceding days the patient had been fit and well. On close questioning he recalled that that morning he had been struck hard in the face by a soccer ball while watching his son's team.

The patient had no significant past medical history and took no medications. There was no family history of neurological disease.

On examination, the patient's right pupil was constricted compared to his left, with both pupils reactive to light. There was a partial ptosis of the right eye. Cranial nerve examination was otherwise unremarkable except for possible right hypoglossal palsy. Examination of the remainder of the peripheral nervous system was remarkable.

Details of initial investigations are given below.

CT brain (non-contrast): no acute intracranial pathology identified; normal ventricular system; no boney injury.

Lumbar puncture:

CSF red cells	2 / mm ³
CSF white cells	4 / mm ³
CSF gram stain	unremarkable
CSF glucose	60 % serum level
CSF protein	0.65 g / L
CSF	negative for haemoglobin break down products

What is the correct diagnosis?

Vertebral artery dissection

	Internal carotid artery dissection
	Posterior reversible encephalopathy syndrome
	Reversible cerebrovascular vasoconstriction syndrome
	Posterior communicating artery aneurysm

Dashboard

Question 156 of 193

□ □

An 89-year-old gentleman presented to the general medical clinic with complaints of palpitations. He was diagnosed with atrial fibrillation (AF) three months ago and started on bisoprolol. This was part of a plan to rate control, rather than rhythm control, his AF. The bisoprolol has been up-titrated as his symptoms did not come under control with his dose. Palpitations occur almost every day but are not associated with any other symptoms. He also has a history of ischaemic heart disease with a myocardial infarction five years ago and type 2 diabetes mellitus. He currently takes bisoprolol, metformin, aspirin and simvastatin. He has declined anticoagulation with warfarin or NOAC despite the risk as his wife died from an intracranial bleed whilst taking warfarin.

On examination, his heart rate is 94/min and irregular. His chest is clear on auscultation and there is no peripheral oedema. How should he be further managed?

	Amiodarone
	Dronedarone
	Amlodipine
	Diltiazem
	Left atrial ablation

Question 159 of 193

□ □

A 60-year-old woman is referred to the general respiratory clinic with increasing shortness of breath over the last nine month months. This has been associated with pedal oedema. There is no orthopnoea, paroxysmal nocturnal dyspnea or cough. Her past medical history includes bilateral extensive pulmonary emboli and she is currently taking warfarin. She has no other lung disease and she does not smoke.

On examination her chest is clear but auscultation demonstrates a loud second heart sound. There is also a right ventricular heave with visible V-waves on jugular venous pressure.

A recent CT pulmonary angiogram showed resolution of the thrombus. Echocardiogram demonstrates severe right heart dilatation and impaired function with moderate tricuspid regurgitation.

What test will most likely provide a formal diagnosis?

	Cardiac MR imaging
	Right heart catheterisation
	Left heart catheterisation
	Brain natriuretic peptide (BNP) measurement
	6-minute walk test

Dashboard

Question 161 of 193

A 58 year-old male is seen in cardiology outpatients clinic. He has a background of type 2 diabetes and hypercholesterolaemia. He complains of a 6 month history of a constricting discomfort in the front of his chest, precipitated by walking up the hill to his house. The pain is relieved by rest within about 5 minutes. He is currently prescribed a sublingual nitrate spray and is taking 10mg bisoprolol once a day. Cardiovascular and respiratory examination is unremarkable. a 12-lead ECG is normal.

What would be the most appropriate additional medication?

<input type="checkbox"/>	Amlodipine
<input type="checkbox"/>	Isosorbide mononitrate
<input type="checkbox"/>	Ivabradine
<input type="checkbox"/>	Nicorandil
<input type="checkbox"/>	Ranolazine

Question 162 of 193

A 72 year old admitted to hospital with VF arrest. The ambulance crew reported an out-of-hospital downtime for 3 minutes before CPR was commenced. In A&E resus, CPR was successful and the patient was intubated after the return of spontaneous circulation. 3 days later, on extubation, the ITU consultant notes confusion and bilateral upper limb weakness, confirmed to be new with a collateral history. A CT head, followed by MRI head, demonstrates bilateral small areas of ischaemic change in bilateral posterior parietal lobes, between middle and posterior cerebral artery territories. CT angiography demonstrates 45% RICA stenosis, 60% L ICA stenosis. The cardiac monitor demonstrates atrial fibrillation and echocardiogram demonstrates septal akinesia, consistent with recent MI. What is the likely cause of this patients stroke?

	Cardiac mural thrombus
	Left carotid artery stenosis
	Right carotid artery stenosis
	Hypotension during cardiac arrest
	Cardioembolic disease

Dashboard

□ Question 163 of 193

□ □

An 82-year-old lady presented with shortness of breath and palpitations. These came on suddenly whilst she was watching television. She had a sedentary lifestyle and recently had been confined to bed with an upper respiratory tract infection. After this she had noticed that her ankles and legs were more swollen than usual, in particular her left leg. On further questioning she said that she had always needed three pillows to sleep but had recently required an extra pillow.

Her past medical history included hypertension, hypothyroidism, asthma and known coronary artery disease.

On examination her pulse was irregularly irregular. The jugular venous pressure was 6cm above the manubriosternal angle. Heart sounds were normal with no added sounds. On auscultation of the lung fields there were coarse crepitations at both bases. There was bilateral pitting oedema to the knees more marked on the left. The circumference of the left leg was 2cm greater than the right.

Observations:

- Heart rate: 128 beats per minute
- SaO₂: 92% on room air
- Respiratory rate: 22 breaths per minute
- Temperature: 36.8 degrees Celsius
- Blood pressure: 110/68 mmHg

Investigations:

- 12-lead electrocardiogram: atrial fibrillation with a fast ventricular response, left ventricular hypertrophy
- Chest X-ray: cardiomegaly, Kerley B lines, small bilateral pleural effusions, pulmonary oedema
- Echocardiogram: poor biventricular function with an ejection fraction of 35%
- Computed Tomography Pulmonary Angiogram: small segmental pulmonary embolus

This lady was anticoagulated appropriately. Following this acute episode she improved clinically but remained in atrial fibrillation.

Given the clinical information available which of the following is the most appropriate drug to control her heart rate in the long term?

--	--

	Metoprolol
	Digoxin
	Diltiazem
	Flecainide
	Warfarin

Question 164 of 193

□ □

An 84-year-old male was admitted to the coronary care unit (CCU) after being admitted as a primary percutaneous coronary intervention (PPCI) call for sudden onset chest pain and ST elevation on anterior leads of his ECG. Angiography demonstrated a mid-left anterior descending artery acute occlusion likely secondary to plaque rupture that was stented with a drug-eluting stent. Two hours after being admitted to CCU, he complained of nausea and vomited twice, which settled after being prescribed cyclizine by a passing medical senior house officer. Thirty minutes afterwards, you are asked to see the patient as the patient has become increasingly short of breath. He complains of no new chest pain, nausea, vomiting, sweating or palpitations. Interrogation of his cardiac telemetry reveals a new sinus tachycardia only without other arrhythmias. On examination, the patient is in respiratory distress, with bibasal inspiratory crackles and raised jugular venous pulse.

His observations are as follows: blood pressure is 186/80 mmHg, heart rate 120 beats per minute and regular, Sats 92% on 3 litres, respiratory rate 33/min.

A repeat 12-lead ECG reveals no new ST elevation changes or other ischaemic changes. A portable chest radiograph demonstrates bibasal alveolar oedema and bilateral small pleural effusions. What is the cause of the patient's deterioration?

	In-stent thrombosis
	Pulmonary embolus
	New independent cardiac ischaemic occlusion
	Cyclizine induced heart failure
	Cardiac tamponade secondary to cardiac instrumentation

Dashboard

Question 172 of 193

□ □

A 64-year-old hypertensive male presents to the emergency department with a history of sudden onset tearing chest pain. He is a chronic smoker with a 25 pack year history. He takes valsartan 160mg daily and amlodipine 5mg daily.

On examination, he is distressed and in severe pain. Blood pressure is 200/120 mmHg. The peripheral pulses are weak and his heart rate is 125 bpm.

Sublingual nitrates and oral aspirin are given to him in the emergency department and his twelve-lead ECG is performed which reveals tachycardia, left ventricular strain and deep S waves in lead V1-V3 and tall R waves in V4-V6.

Chest x-ray shows widening of the mediastinum with an irregular aortic contour.

Contrast-enhanced CT scan of the chest reveals an aortic intimal flap distal to left subclavian artery.

Which of the following is the most appropriate treatment option for this patient?

	Blood pressure control with IV beta-blockers
	Percutaneous stent insertion
	Surgical repair
	Blood pressure control with IV hydralazine
	Continuous infusion of isosorbide dinitrate

□ □

A 63-year-old gentleman is reviewed by his GP. He has a past medical history of ischaemic heart disease having suffered a myocardial infarction two years ago, hypertension, elevated cholesterol. He is a current smoker with a 25 pack-year history. He has been having no problems at home and has been looking forward to retiring from his job in the insurance industry. He lives at home with his wife. He has two children; one suffers from hypothyroidism but otherwise, they are well. His father died of a heart attack at the age of 55 years. He came in for a medication review. He takes aspirin, ramipril, atorvastatin and amlodipine. He has no problems with his medications.

On examination, he is found to have an irregularly irregular rhythm and ECG confirms irregular QRS complexes without p-waves. What factors should be including when assessing his risk for stroke and when considering anticoagulation?

	Family history of ischaemic heart disease
	Smoking history
	History of hypertension
	Sex
	History of high cholesterol

Question 174 of 193

□ □

A 68 year old gentleman with a past medical history of type 2 diabetes mellitus and hypertension attends the Emergency Department complaining of general malaise and feeling unwell. He had undergone successful primary coronary intervention (PCI) post myocardial infarction 5 weeks previously. He has a temperature of 38.2 degrees Celsius, blood pressure 164/87 mmHg and the doctor notes a lacy reticular rash extending over his legs.

Hb	12.2g/dl
Eosinophils	$1.2 \times 10^9/l$
WBC	$14.5 \times 10^9/l$
Urea	8mmol/l
Creatinine	142 μ mol/l

What is the most likely cause of his symptoms?

	Allergic rash to contrast
	Infected femoral site
	Cholesterol embolus
	Infective endocarditis
	Polyarteritis nodosa

Question 175 of 193

A 36-year-old man presents to the Emergency Department with chest pain. This started around 2 hours ago and is described as severe. The pain is central, with no radiation. It is not worse on deep inspiration.

He smokes 10 cigarettes/day but is otherwise fit and well. His father had a myocardial infarction at the age of 61 years. Examination of the cardiovascular system is unremarkable with a blood pressure of 136/84 mmHg, pulse 96/min, respiratory rate 14/min and saturations 98% on room air.

An ECG is taken:

□ Question 176 of 193

□ □

A 72-year-old man attends cardiology clinic for routine follow-up of ischaemic heart disease. The patient had suffered a non-ST elevation myocardial infarction the previous year treated with a drug eluting stent (see below angiogram report). The patient reported being generally well over previous months although did experience retro-sternal chest pain on exertion, typically on walking up hills or climbing stairs. The patient denied any episodes of pain at rest and did not feel his symptoms were worsening. The patients regular medications were aspirin 75 mg daily, clopidogrel 75 mg daily, atorvastatin 80 mg daily and ramipril 5 mg daily. As required medications were sildenafil and a nitrate spray (which he reported as giving effective relief from his chest pain episodes).

Clinical examination did not demonstrate any evidence of cardiac failure. Blood pressure in clinic was 125 / 75 mmHg.

Results of investigations conducted 1 year previously following presentation with NSTEMI are included below.

Angiography: 90 % stenosis to left anterior descending artery treated with drug-eluting stent; 60 % stenosis to mid-right coronary artery; minor disease to other vessels.

Transthoracic echocardiogram: valvular function unremarkable; mild hypokinesis to anterior myocardium; overall ejection fraction approximately 40-45 %.

Electrocardiogram: sinus rhythm at 75 beats per minute; normal axis; normal QRS; no significant ST changes; inverted T waves in V3-V5.

What is most appropriate next line therapy for the patients chest pain?

	Amlodipine
	Bisoprolol
	Percutaneous coronary intervention
	Long-acting isosorbide mononitrate
	Nicorandil

Overall score: **0%**

□ Question 177 of 193

A 58-year-old man attends cardiology clinic with retro-sternal chest pain on exertion. He reports onset of his symptoms when walking more than 50 metres on flat ground or when playing on the floor with his grand-children. The symptoms have been present at the current level for at least the previous 9 months and the patient denied any episodes of pain at rest. The patients GP has previously attempted treatment with bisoprolol and amlodipine but both medications were discontinued for unwanted effects (bradycardia and ankle swelling respectively). The patient has no other medical history except for hypercholesterolaemia. Regular medications are aspirin 75 mg daily and pravastatin 10 mg daily with nitrate spray and sildenafil used as required. He is formerly a heavy smoker but managed to quit the previous year.

Clinical examination in clinic is unremarkable with no evidence of cardiac failure. Blood pressure in clinic is 102 / 72 mmHg.

Please see below for results of previous investigations.

Electrocardiogram: sinus rhythm at 58 beats per minute; borderline left axis deviation; normal QRS complex; non-specific lateral ST segment abnormalities; normal T waves.

Transthoracic echocardiogram: normal valvular function; no regional wall motion abnormality; ejection fraction 55-60 %.

Urea	6.7 mmol / L
Creatinine	80 micromol / L
Sodium	138 mmol / L
Potassium	4.1 mmol / L

Cardiac stress magnetic resonance imaging: significant evidence of ischaemia in the region of the lateral left ventricle; estimated 20 % of LV myocardium with significant evidence of ischaemia.

What is the most appropriate management of the patients chest pain?

	Ticagrelor
	Nicorandil

	Percutaneous coronary intervention
	Ivabradine
	Long-acting isosorbide mononitrate

Question 179 of 193

□ □

A 62-year-old gentleman presents to the emergency department with central chest pain. He describes his pain as a heavy pressure in the middle of his chest which radiates to his left arm. It has improved with the use of his GTN spray, but he did not want to use more than two puffs as he is concerned about getting a headache with its use. He has a past medical history of angina, previous myocardial infarction three years ago and he is a current smoker with a 25 pack-year history.

His ECG demonstrates ST depression in V3 to V5 of 2mm, pathological Q waves and T wave inversion. His troponin is raised at 350ng/L. He is given aspirin, clopidogrel and morphine. His pain settles and he starts to feel comfortable. He has a high GRACE (Global Registry of Acute Coronary Events) score at 122, meaning that he has a 7.9% chance of death within 6 months. Following discussion with the cardiology registrar will be scheduled for an angiogram within 12 hours. How should his acute coronary syndrome be further managed?

	Fondaparinux
	No further anticoagulants
	Unfractionated heparin
	Heparin sodium
	Heparin infusion

Dashboard

Question 180 of 193

□ □

A 25-year-old man presents to the emergency department. He is concerned as he developed chest pain whilst at work. He noticed severe sharp chest pain which came on whilst standing and serving customers in the store where he works. He is normally fit and well with no past medical history or regular medications. He has a family history of asthma and diabetes. He describes that the pain started six hours ago and has not settled. It improved slightly with analgesia.

On examination the patient is sitting up in his bed, leaning forward. He prefers this position as it eases his chest pain. On auscultation the heart sounds are normal. The lung bases are clear and the abdomen is soft and non-tender. His vital parameters are within normal range. Troponin is found to be normal. ECG shows sinus rhythm with no other abnormalities.

What investigation is likely to be diagnostic?

	Chest X-ray
	Angiogram
	CT pulmonary angiogram
	Echocardiogram
	Full blood count

Question 181 of 193

□ □

A 25-year-old male presents to the emergency department with palpitations. His observations are performed, heart rate 180/min, blood pressure 134/78 mmHg, respiratory rate 16/min. His past medical history includes asthma for which he takes salbutamol PRN and fluticasone BD. Examination reveals a clear chest. Heard sounds are too rapid to distinguish S1 and S2. ECG reveals a narrow complex tachycardia, consistent with supraventricular tachycardia (SVT). Multiple attempts at vagal manoeuvres have failed to cardiovert the patient. He remains symptomatic.

Bloods are taken:

Hb	135 g/l
Platelets	344 * 10 ⁹ /l
WBC	10.1 * 10 ⁹ /l

Na ⁺	141 mmol/l
K ⁺	4.2 mmol/l
Creatinine	65 µmol/l
CRP	2 mg/l

Arterial blood gases on room air:

pO ₂	12.1 kPa
PCO ₂	4.1 kPa
pH	7.39
Base excess	-0.2

Chest X-ray: No abnormality detected

Which pharmacological agent would be most appropriate for cardioverting this man?

	Verapamil
	Adenosine
	Digoxin
	Amiodarone
	Bisoprolol

Question 183 of 193

A 54-year-old male previously treated for lymphoma is seen in clinic with a 6-month history of exertional dyspnoea which is progressive. He was treated four years ago and was told that there was no evidence of disease on the final CT scan. His GP treated him for a presumed lower respiratory tract infection two weeks ago. He returned from a business trip to Thailand six months ago, during which he consumed more alcohol than he usually does. He takes no medications and is otherwise fit and well, and is a non-smoker. On examination there is mild pedal oedema, his chest is clear and jugular venous pressure(JVP) is raised on inspiration. Auscultation of his heart reveals an extra heart sound very soon after S2.

What is the likely cause of his symptoms?

	Superior vena cava obstruction
	Cardiac tamponade
	Left ventricular failure
	Chronic obstructive pulmonary disease
	Constrictive pericarditis

□ Question 184 of 193

□ □

A 52-year-old gentleman works as a lorry driver. His past medical history includes hypertension and raised BMI. He is admitted to the Emergency Department with chest pain. An ECG confirms ST depression in V1 to V4, with no pathological Q waves. Subsequent blood tests reveal a troponin of 10,000 consistent with a non-ST-elevation myocardial infarction (NSTEMI). He is commenced on appropriate secondary prevention, including aspirin 75mg OD, clopidogrel 75mg OD and fondaparinux 2.5mg SC. The patient is transferred to the cardiology unit and awaits in-patient angiography.

You are asked to review him urgently as he describes acute breathlessness. He denies chest pain. Observations are as follows: heart rate 130 beats per minute, blood pressure 95/62 mmHg, temperature 36.1°C, respiratory rate 28/min, saturations 94% on 10 litres oxygen. On examination, heart sounds are normal with no added sounds. JVP is mildly elevated. There is no evidence of ascites or peripheral oedema. A repeat ECG confirms sinus tachycardia (heart rate 130bpm) but no dynamic changes. A portable chest x-ray reveals cardiomegaly with upper lobe diversion and peri-hilar shadowing. An urgent bedside echocardiogram demonstrates significant LV systolic dysfunction with a 2cm of pericardial effusion but no features of tamponade.

What is the single next best management step?

	Continuous positive airway pressure (CPAP)
	Ultrasound-guided pericardiocentesis
	Urgent angiography
	IV fluids
	Inotrope and IV diuretic

Dashboard

□ Question 186 of 193

A 23-year-old Afro-Caribbean female presents with a four-month history of fatigue, transient fever lasting hours, 12kg weight loss and non-specific bilateral headaches. She has presented to the Emergency Department four times in the past 3 months with non-specific abdominal pains that are worse after eating and also blue-lighted into her local hyperacute stroke unit as a thrombolysis patient after sudden onset loss of monocular blindness in her left eye, which resolved before any treatment was given. She has no other past medical history, does not smoke and drinks minimally.

On examination, cranial nerve examination and fundoscopy are both unremarkable. Upper and lower limb neurology are intact with downgoing plantars. Her heart sounds demonstrates a gallop rhythm, an early diastolic murmur and a mild radial-radial delay. Chest auscultation is clear. She appears very warm and measures 38.4°C in your clinic with facial flushing. Blood tests are as follows:

Hb	94 g/l
Platelets	245 * 10 ⁹ /l
WBC	18.4 * 10 ⁹ /l
Eosinophil	0.1 * 10 ⁹ /l
ESR	121 mm/hr

Na ⁺	141 mmol/l
K ⁺	4.0 mmol/l
Urea	5.2 mmol/l
Creatinine	68 µmol/l
CRP	56 mg/l

Complement levels were reported as normal and an antibody screen including ANCA and ANA was negative. Urine dip is negative. Chest X-ray demonstrates focal consolidation. Her heart rate is 95 and regular, her blood pressure is 185/110 mmHg.

What is the unifying diagnosis?

	Systemic lupus erythematosus
	Polyarteritis nodosa
	Poorly controlled primary hypertension
	Ascending aortic aneurysm
	Takayasu arteritis

□ Question 186 of 193

A 23-year-old Afro-Caribbean female presents with a four-month history of fatigue, transient fever lasting hours, 12kg weight loss and non-specific bilateral headaches. She has presented to the Emergency Department four times in the past 3 months with non-specific abdominal pains that are worse after eating and also blue-lighted into her local hyperacute stroke unit as a thrombolysis patient after sudden onset loss of monocular blindness in her left eye, which resolved before any treatment was given. She has no other past medical history, does not smoke and drinks minimally.

On examination, cranial nerve examination and fundoscopy are both unremarkable. Upper and lower limb neurology are intact with downgoing plantars. Her heart sounds demonstrates a gallop rhythm, an early diastolic murmur and a mild radial-radial delay. Chest auscultation is clear. She appears very warm and measures 38.4°C in your clinic with facial flushing. Blood tests are as follows:

Hb	94 g/l
Platelets	245 * 10 ⁹ /l

Question 186 of 193

A 23-year-old Afro-Caribbean female presents with a four-month history of specific bilateral headaches. She has presented to the Emergency Department with episodes of blue-lighting and also blue-lighted into her local hypotension. She has experienced monocular blindness in her left eye, which resolved before any treatment. She drinks minimally.

On examination, cranial nerve examination and fundoscopy are both normal. She has tender, red, swollen plantars. Her heart sounds demonstrate a gallop rhythm, an early diastolic murmur. She appears very warm and measures 38.4°C in your clinic with fever.

Hb	94 g/l
Platelets	245 * 10 ⁹ /l
WBC	18.4 * 10 ⁹ /l
Eosinophil	0.1 * 10 ⁹ /l
ESR	121 mm/hr

Na ⁺	141 mmol/l
K ⁺	4.0 mmol/l
Urea	5.2 mmol/l
Creatinine	68 µmol/l
CRP	56 mg/l

Complement levels were reported as normal and an antibody screen including ANCA and ANA was negative. Urine dip is negative. Chest X-ray demonstrates focal consolidation. Her heart rate is 95 and regular, her blood pressure is 185/110 mmHg.

What is the unifying diagnosis?

<input type="checkbox"/>	Systemic lupus erythematosus
<input type="checkbox"/>	Polyarteritis nodosa
<input type="checkbox"/>	Poorly controlled primary hypertension
<input type="checkbox"/>	Ascending aortic aneurysm
<input checked="" type="checkbox"/>	Takayasu arteritis

Overall score: **0%**

Question 187 of 193

□ □

A 56-year-old gentleman is admitted to Emergency Department with back pain. His past medical history included type 2 diabetes and hypertension. Initial observations are as follows: heart rate 112 beats per minute, blood pressure 155/82 mmHg, respiratory rate 26/min, oxygen saturations 95% on 2 litres oxygen via nasal cannula, temperature 37.2°C.

Examination demonstrates muffled heart sounds I and II. JVP is not elevated and there is no peripheral oedema. Auscultation of the chest is clear with no crackles or wheeze and good air entry bilaterally. An ECG confirms sinus tachycardia with a heart rate of 102 beats per minute and 2mm inferior ST depression. Portable chest x-ray shows poor inspiratory effort with cardiomegaly and clear lung fields.

What single investigation would you arrange next?

	CT aortogram
	CT pulmonary angiogram (CTPA)
	Ventilation/Perfusion scan (V/Q scan)
	Echocardiogram
	12 hour troponin

Dashboard

Overall score: 0%

Question 188 of 193

□ □

A 32 year old woman presents to the emergency department with palpitations. Her past medical history includes type 2 diabetes mellitus and acne vulgaris. She is currently taking Yasmin (a combined oral contraceptive pill) and has no known allergies.

Examination reveals a strong radial pulse, which is tachycardic and regular. She has a raised body mass index. Her cardiopulmonary system is unremarkable.

Observations:

- Heart rate: 168/min
- Blood pressure: 138/88 mmHg
- Oxygen saturations: 98% on room air
- Temperature: 37°C

An ECG shows a supraventricular tachycardia.

The foundation year two doctor has already tried vagal maneuvers and has just given 6mg of adenosine to no effect.

What is the most appropriate next step in management?

	Amiodarone IV infusion
	12mg adenosine IV
	Beta blocker IV
	Cardioversion
	Further 6mg adenosine IV

Question 189 of 193

A 58-year-old man presents with intermittent chest pains for the past two days. Whilst you are taking the history he complains of worsening pain and you arrange an ECG immediately:

© Image used on license from Dr Smith, University of Minnesota

He is tachycardic and sweaty with a blood pressure of 128/88mmHg. What does the ECG show?

	Narrow complex tachycardia with ST elevation
	Right bundle branch block with ST elevation
	Left bundle branch block with ST elevation
	Ventricular tachycardia with ST elevation
	Posterior myocardial infarction

Question 190 of 193

□ □

A 72 year old female presents with left chest pain associated with sweating in her hands and nausea. Her past medical history includes T2 diabetes mellitus, hypertension and hypercholesterolaemia, with her regular medications including metformin 850mg BD, gliclazide 40mg OD, ramipril 10mg, amlodipine 5mg and atorvastatin 40mg ON. On examination, her heart sounds are normal with a pansystolic murmur. Her ECG demonstrates ST depression in V2 to V5. Her BMs have ranged between 6 and 14 mmol/L since her admission 4 hours ago. How should you manage her diabetic medications?

	No changes to medication
	Increase metformin to 850mg TDS
	Increase gliclazide to 40mg BD
	Actrapid PRN 4 units when BM >11mmol/L
	Stop all medications, start insulin sliding scale

□ Question 190 of 193

□ □

A 72 year old female presents with left chest pain associated with sweating in her hands and nausea. Her past medical history includes T2 diabetes mellitus, hypertension and hypercholesterolaemia, with her regular medications including metformin 850mg BD, gliclazide 40mg OD, ramipril 10mg, amlodipine 5mg and atorvastatin 40mg ON. On examination, her heart sounds are normal with a pansystolic murmur. Her ECG demonstrates ST depression in V2 to V5. Her BMs have ranged between 6 and 14 mmol/L since her admission 4 hours ago. How should you manage her diabetic medications?

	No changes to medication
	Increase metformin to 850mg TDS
	Increase gliclazide to 40mg BD
	Actrapid PRN 4 units when BM >11mmol/L
	Stop all medications, start insulin sliding scale

Question 191 of 193

A 35-year-old man is investigated for recurrent palpitations associated with pre-syncopal symptoms and dyspnoea. Blood tests are unremarkable and a resting 12 lead ECG is shown below:

© Image used on license from Dr Smith, University of Minnesota

Given the likely diagnosis it is decided that radiofrequency ablation is the most appropriate treatment. What part of the heart should be ablated?

	Sinoatrial node
	Atrioventricular node
	Junction of right atrium and right ventricle
	Left atrial appendage
	Junction of left atrium and left ventricle

Question 192 of 193

A 19-year-old student is brought to the Emergency Department by her friends. Around one hour ago she 'collapsed' whilst playing hockey. Her friends describe her complaining that she felt light-headed and then 'fainting' to the ground. She lost consciousness for a few seconds before returning to normal quite quickly. There is no past medical history of note other than the use of Microgynon 30 (a combined oral contraceptive pill). For the past 4-5 days the patient has experienced shortness-of-breath and a central chest pain which is worse when she coughs. On examination her pulse is 120/min, blood pressure 96/60 mmHg and chest auscultation reveals scattered wheezes. An ECG done on admission is shown below:

© Image used on license from Dr Smith, University of Minnesota

What is the most likely diagnosis?

	Hypertrophic obstructive cardiomyopathy
	Vasovagal attack
	Acute coronary syndrome
	Pulmonary embolism
	Asthma attack

Overall score: 14.4%

Question 192 of 193

A 19-year-old student is brought to the Emergency Department whilst playing hockey. Her friends describe her complaining that she lost consciousness for a few seconds before returning to consciousness. She has no other note other than the use of Microgynon 30 (a combined oral contraceptive pill). She experienced shortness-of-breath and a central chest pain which resolved within 10 minutes. Her heart rate is 120/min, blood pressure 96/60 mmHg and chest auscultation is normal. The CT scan is shown below:

What is the most likely diagnosis?

	Hypertrophic obstructive cardiomyopathy
	Vasovagal attack
	Acute coronary syndrome
	Pulmonary embolism
	Asthma attack

Overall score: 14.4%

Question 192 of 193

A 19-year-old student is brought to the Emergency Department by her friends. Around one hour ago she 'collapsed' whilst playing hockey. Her friends describe her complaining that she felt light-headed and then 'fainting' to the ground. She lost consciousness for a few seconds before returning to normal quite quickly. There is no past medical history of note other than the use of Microgynon 30 (a combined oral contraceptive pill). For the past 4-5 days the patient has experienced shortness-of-breath and a central chest pain which is worse when she coughs. On examination her pulse is 120/min, blood pressure 96/60 mmHg and chest auscultation reveals scattered wheezes. An ECG done on admission is shown below:

Question 193 of 193

□ □

An 84-year-old presents to the emergency department with and acute deterioration in shortness of breath on a background of 9 months of progressively reduced exercise tolerance. Her past medical history includes hypertension, previous myocardial infarctions 7 months ago, chronic kidney disease and COPD. She has a 50 pack year smoking history giving up 2 years ago. Her exercise tolerance is 150 yards, limited by shortness of breath.

On examination, an ejection systolic murmur can be heard in the aortic area with bibasal crackles on chest auscultation. An admission chest x-ray is consistent with pulmonary oedema and intravenous diuresis is commenced. A transthoracic echocardiogram demonstrates ejection fraction of 33% with impaired left ventricular function, no vegetations, a bicuspid heavily calcified aortic valve with an area of 0.7cm² and a peak gradient of 32mmHg. Angiography demonstrates non-flow limiting stenosis of 65% in the left anterior descending artery but no lesions requiring revascularisation. Lung function testing following successful diuresis reveals forced vital capacity at 55% of predicted and forced expiratory volume in 1 second at 48% of predicted.

The patient is keen for a definitive intervention if appropriate. What is the appropriate next action?

	No action
	Balloon aortic valvuloplasty
	Aortic valve replacement
	Transcatheter aortic valve implantation
	Coronary artery bypass graft and aortic valve replacement

Dashboard

Question 1 of 215

A 31-year-old lady presents to the emergency department with abdominal pain.

Her medical and surgical history is unremarkable other than mild depression and hay fever. Medications include paroxetine and PRN loratadine.

She complains of generalised colicky abdominal pain and has vomited once in the department.

On examination blood pressure is 155/86mmHg, heart rate is 95bpm and temperature is 37.9°C. Digital rectal examination reveals hard stool in the rectum.

Investigations reveal:

Hb	131 g/l
Platelets	362 * 10 ⁹ /l
WBC	7.3 * 10 ⁹ /l
Na ⁺	121 mmol/l
K ⁺	3.3 mmol/l
Urea	6.2 mmol/l
Creatinine	87 µmol/l
Urine dipstick	protein ++, leucocytes ++

What is the most likely diagnosis?

	Cholecystitis
	Acute porphyria
	Intestinal obstruction

	Pyelonephritis
	Systemic lupus erythematosus

□ Question 2 of 215

□ □

A 19-year-old man is reviewed prior to discharge. He presented with vomiting and abdominal pain and was found to have diabetic ketoacidosis. He was managed as an inpatient for five days before being well enough for discharge. He is also diagnosed with type 1 diabetes mellitus on this admission as a cause of the diabetic ketoacidosis. He has been educated by the diabetic nurse on how to manage his diabetes and insulin at home, but he is concerned about what his target plasma glucose should be after eating.

What is the recommended target after eating to be achieved by home monitoring?

	3-6mmol/litre
	5-10mmol/litre
	5-9mmol/litre
	7-12mmol/litre
	2-9 mmol/litre

Question 3 of 215

□ □

A 29-year-old woman presentsis referred to the Endocrinology clinic as she has just found out she is pregnant. She was diagnosed with hypothyroidism three years ago and is currently stable on a dose of levothyroxine 75mcg od. She has also been taking folic acid 400mcg od for the past 6 months. Her last bloods taken 6 months ago show the following:

TSH	1.4 mU/l
-----	----------

You request a repeat TSH and free T4 measurement. What is the most appropriate next step?

	Decrease levothyroxine to 50mcg od
	Keep levothyroxine at 75mcg od
	Increase levothyroxine to 100mcg od
	Keep levothyroxine at 75mcg od + increase folic acid to 5mg od
	Stop levothyroxine until TSH known

□ Question 4 of 215

□ □

A 17 year old girl is brought into A&E by her mother. The patient appears terrified after she experienced an episode on waking earlier in the morning when she could not move at all for 2 hours. This was her second episode. She reports no loss of consciousness and was aware throughout the episode. She has no other past medical history documented. She is not aware of a previous episode of epilepsy. On examination, her heart sounds and breath sounds are unremarkable. Neurological examination demonstrated no abnormalities. She normal dentition and her BMI is 19.5. A 12 lead ECG demonstrated a jerky baseline with flat T waves. What is the diagnosis?

	Partial or absence seizures
	Guillain Barre syndrome
	Botulinum toxicity
	Myasthenia gravis
	Hypokalaemia

□ Question 5 of 215

□ □

A 56-year-old lady presents with a 3 month history of abdominal pains, low mood and constipation. Past medical history includes hypertension and depression following the death of her husband 2 years ago. Routine blood tests are performed by the GP and upon review the patient is referred into hospital.

Blood tests are as below:

Hb	100 g/l	Na ⁺	135 mmol/l
Platelets	230 * 10 ⁹ /l	K ⁺	4.7 mmol/l
WBC	10 * 10 ⁹ /l	Urea	6 mmol/l
Calcium (adjusted)	2.96 mmol/l	Creatinine	110 µmol/l
Phosphate	1.35 mmol/l	CRP	30 mg/l
Albumin	35 g/L		

Which diagnostic test should be performed first?

	Parathyroid hormone level
	Myeloma screen
	CT chest, abdomen and pelvis
	Urinary calcium levels
	Skeletal X-ray

Question 10 of 215

A 21-year-old male presents to his GP complaining of muscle cramps that prevent him from competing in his local park 5 km race. He has always had muscle pains when warming up with exercise but these gradually diminish after 20 minutes. There was no weakness and no abnormalities on neurological exam.

Creatinine kinase was elevated at 1215 IU/L and myoglobinuria was noted on urinalysis. The electromyography (EMG) demonstrated myotonic discharges and fibrillations.

What is the likely diagnosis?

	Hypokalaemic periodic paralysis
	Von Gierke disease
	McArdle disease
	Pompe disease
	Gaucher disease

□ Question 12 of 215

A 76 year old woman was admitted to hospital after presenting to the Emergency Department with shortness of breath, productive cough and palpitations. A chest x-ray demonstrated a left lower lobe pneumonia and ECG showed atrial fibrillation with a fast ventricular response. Initial management included intravenous antibiotics, intravenous fluids and oral digoxin loading.

Two days after admission, the patient's condition had significantly improved and she was able to start mobilising on the ward. The palpitations that she had been experiencing at presentation had also ceased. Following review by the Senior House Officer on the ward round, a repeat ECG was requested when demonstrated that the patient had cardioverted back to sinus rhythm. Digoxin therapy was subsequently held.

To investigate for an underlying cause of atrial fibrillation, thyroid function tests were added to blood tests from admission, with results as listed below.

Haemoglobin	125 g / dL
White cell count	13.7* 10 ⁹ /l
Neutrophils	11.9* 10 ⁹ /l
Platelets	351 * 10 ⁹ /l
Urea	4.6 mmol / L
Creatinine	130 micromol / L
Sodium	139 mmol / L
Potassium	3.6 mmol / L
C-reactive protein	105 mg / L
Thyroid stimulating hormone	0.25 microU / L
T4 free serum	14.1 pmol / L
T3 free serum	7.4 pmol / L

What is the most appropriate next investigation to assess deranged thyroid function tests?

	Thyroid ultrasound
	Thyroid peroxidase antibody levels
	Repeat TFT in 6 weeks
	Thyroid scintiscanning
	Thyroglobulin antibody levels

Dashboard

□ Question 13 of 215

A 23-year-old female presents with worsening acne and a marked increase in the development of body and facial hair which she finds very distressing. She is also overweight and is markedly stressed by her physical appearance and the development of stretch marks over her abdomen. She has tried multiple hair removal techniques with only mild success.

On examination, she has a body mass index of 28 kg/m², coarse hair over the anterior and posterior part of her chest and under her chin. Her Blood Pressure is 135/90mmHg.

Her lab results are as follows:

9:00 am Cortisol	345 nmol/l (170 700 nmol/l)
LH	17 iU/l (1 20 iU/l)
Basal FSH	7.1 iU/l (1.0 8.8 iU/l)
DHEAS	545 µg/dl (31 228 µg/dl)
Prolactin	160 mU/l (<360 mU/l)
17 OH Progesterone	1025 ng/dl (<80 ng/dl)
Testosterone	3.9 nmol/l (0.9 3.1 nmol/l)

Ultrasound abdomen and pelvis reveals two cysts in the right ovary.

Which of the following is the most appropriate treatment option for her condition?

	Combined oral contraceptive pill
	Finasteride
	Surgical resection of the ovarian cysts
	Reverse circadian rhythm steroids

Dashboard

Overall score: **0%**

Question 14 of 215

A 26-year-old man is reviewed in gastroenterology clinic. He is known to have Crohn's disease which has been stable over the last six months and not required any recent steroids or hospital admissions. Routine blood tests demonstrate a vitamin D level at 22 nmol/L. All other blood tests, including calcium, are within normal range. What is the most appropriate management plan?

<input type="checkbox"/>	No treatment needed
<input type="checkbox"/>	Dietary advise only
<input type="checkbox"/>	Maintenance dose vitamin D
<input checked="" type="checkbox"/>	Loading dose vitamin D
<input type="checkbox"/>	Combined calcium and vitamin D

The correct answer is loading dose vitamin D. He has a serum concentration <30 nmol/L and therefore has vitamin D deficiency, likely secondary to his Crohn's disease. He, therefore, needs a loading dose of vitamin D. As calcium levels are normal there is no current indication for supplementation.

Vitamin D deficiency versus insufficiency

Description	Serum levels	Treatment
Adequate vitamin D	>50 nmol/L	dietary recommendations
Insufficient vitamin D	30-50 nmol/L	maintenance dose vitamin D
Deficient vitamin D	<30 nmol/L	loading dose vitamin D

Please rate this question:

☐ Discuss and give feedback

Osteomalacia

Basics

- normal bony tissue but decreased mineral content
- rickets if when growing
- osteomalacia if after epiphysis fusion

Types

- vitamin D deficiency e.g. malabsorption, lack of sunlight, diet
- renal failure
- drug induced e.g. anticonvulsants
- vitamin D resistant; inherited
- liver disease, e.g. cirrhosis

Features

- rickets: knock-knee, bow leg, features of hypocalcaemia
- osteomalacia: bone pain, fractures, muscle tenderness, proximal myopathy

Investigation

- low calcium, phosphate, 25(OH) vitamin D
- raised alkaline phosphatase
- x-ray: children - cupped, ragged metaphyseal surfaces; adults - translucent bands (Looser's zones or pseudofractures)

Treatment

- calcium with vitamin D tablets

Question 15 of 215

A 56-year-old man is referred to clinic by his General Practitioner as his GP had performed some routine blood tests which showed a K⁺ of 2.8 mmol/l. The patient feels well in himself. His past medical history includes angina and renal stones. On examination his chest is clear and his abdomen is soft and non-tender.

Observations are as follows: temperature 36.3, blood pressure 132/86 mmHg, heart rate 78/min, respiratory rate 16/min, saturations 95% on air

His ECG shows normal sinus rhythm.

Investigations are as follows:

Na ⁺	142 mmol/l
K ⁺	2.8 mmol/l
Creat	117 µmol/l
Urea	9.6 mmol/l
Urinary K ⁺	26 mmol/l (normal <20)
PaO ₂	11.2 kPa
PaCO ₂	3.6 kPa
pH	7.32
HCO ₃ ⁻	18 mmol/l
Base excess	-3 mmol/l

What is the most likely cause of his hypokalaemia?

	Barter's Syndrome
	Liddle's Syndrome

	Renal tubular acidosis type 1
	Renal tubular acidosis type 2
	Renal tubular acidosis type 4

□ Question 16 of 215

A 45-year-old woman presents to the Emergency Department with abdominal pain. Her GP is currently investigating her for lethargy, weakness and abdominal pain. Her symptoms have been getting progressively worse over the past few months. There is no past medical history of note. She smokes 5-10 cigarettes/day and drinks around 20 units of alcohol per week.

A urine dipstick has already been performed: protein trace, blood +, pH 5.5-6.0

Bloods show the following:

Hb	13.6 g/dl	Na ⁺	143 mmol/l
Platelets	225 * 10 ⁹ /l	K ⁺	2.3 mmol/l
WBC	8.4 * 10 ⁹ /l	Urea	6.1 mmol/l
Neuts	6.0 * 10 ⁹ /l	Creatinine	81 µmol/l
Lymphs	1.9 * 10 ⁹ /l	Bicarbonate	7 mmol/l
Eosin	0.3 * 10 ⁹ /l	Chloride	124 mmol/l

An abdominal film is requested due to her recurrent abdominal pains:

□ □

A 45-year-old woman presents to the Emergency Department with abdominal pain. Her GP is currently investigating her for lethargy, weakness and abdominal pain. Her symptoms have been getting progressively worse over the past few months. There is no past medical history of note. She smokes 5-10 cigarettes/day and drinks around 20 units of alcohol per week.

A urine dipstick has already been performed: protein trace, blood +, pH 5.5-6.0

Bloods show the following:

Hb	13.6 g/dl	Na ⁺	143 mmol/l
Platelets	225 * 10 ⁹ /l	K ⁺	2.3 mmol/l
WBC	8.4 * 10 ⁹ /l	Urea	6.1 mmol/l
Neuts	6.0 * 10 ⁹ /l	Creatinine	81 µmol/l
Lymphs	1.9 * 10 ⁹ /l	Bicarbonate	7 mmol/l
Eosin	0.3 * 10 ⁹ /l	Chloride	124 mmol/l

An abdominal film is requested due to her recurrent abdominal pains:

□ Question 17 of 215

□ □

A 64-year-old woman comes to the Emergency department complaining of palpitations at rest, and worsening angina over the past month. She has been treated with amiodarone for the past 3 years for recurrent ventricular tachycardia. She has a blood pressure of 110/70 mmHg, pulse of 95 beats per minute, and a fine tremor. There is no goitre. TSH is suppressed at less than 0.05 U/ml.

You suspect she has amiodarone induced thyrotoxicosis. How best can you determine the underlying pathophysiology?

	IL6 level
	Thyroglobulin level
	TSH level
	Duration of amiodarone therapy
	Colour flow doppler ultrasonography

□ Question 18 of 215

□ □

A 34 year-old woman is seen by her GP for the annual review of her type 1 diabetes. Her most recent HbA1c is 58 mmol/mol and the only problem she has noticed are severe hypoglycaemic episodes during the night around 2-4am, that she noticed she was getting while working night shifts for a local superstore. However, by breakfast time, her blood glucose levels often rise to around 15 mmol/mol. Her insulin regimen is currently a twice daily mixed insulin.

What is the most appropriate change to her current insulin treatment?

	Move to a basal bolus of insulin
	Take 1 dextrose tablet at 9pm
	Reduce nocturnal insulin dose
	Reduce morning insulin dose
	Add gliclazide

□ Question 21 of 215

□ □

A 60-year-old taxi driver presents to the diabetes clinic for review. He is obese with a body mass index of 36 kg/m², and has noticed a significant increase in his fasting blood glucose over the past 3 months from 6.5 mmol/l, to over 9 mmol/l. Apart from hypertension he has no other significant past medical history. Current medication includes metformin 1g BD, ramipril 10mg OD and atorvastatin 20mg OD. On examination his blood pressure is 155/82 mmHg, pulse is 70 beats per minute and regular. His chest is clear, abdomen is soft and non-tender with no masses, and he has no ankle swelling. Bloods reveal a normal creatinine and an HbA1c of 70 mmol/mol.

Which of the following is the most appropriate way to manage his blood glucose?

	Gliclazide
	Liraglutide
	Sitagliptin
	BD mixed insulin
	Acarbose

□ Question 1 of 191

A 35-year-old man was assessed in endocrinology clinic after being referred by his GP for advice on management of the consequences of the patient's use of anabolic steroids. The patient reported that he had been using anabolic steroids intermittently for the previous 10 years to augment his weight-training regime. Having recently become aware of the potential adverse health consequences, the patient now wished to know how he could safely stop his anabolic steroid use.

The patient described his pattern of anabolic steroid use: typically, he had been taking a 'cycle' of one or more oral synthetic testosterone derivatives for between 6-12 weeks, prior to a 3-4 week break in his use of steroids. The patient stated this strategy was an attempt to minimise his risk of side effects. The patient had not received any medical supervision of his anabolic steroid use, relying instead on discussions with friends at his gym and information from online forums. The patient declined to disclose the source from which he had obtained his supply of medications.

The patient stated that he believed his anabolic steroid use had contributed to his male pattern baldness and also had caused intermittent breakouts of acne on his chest and face. The patient was not aware of any other symptoms related to his steroid use, although stated that he was concerned about possible lasting cardiac side effects. The patient had no other significant medical history and took no other regular medications. He did not consume cigarettes, alcohol or recreational drugs.

General examination of the patient revealed a muscular and lean adult male in apparent good health. A cardiovascular system examination noted a forceful but not displaced apex beat. Mild gynaecomastia was present but gastrointestinal examination was otherwise unremarkable. Using an orchidometer the patient's testicular volume was estimated as 16 ml. Although anxious about the possible health consequences of his anabolic steroid use, the patient did not seem to be significantly depressed or anxious.

Haemoglobin	173 g / dL
Sodium	148 mmol / L
Potassium	3.6 mmol / L
Alkaline phosphatase	135 U / L (reference 35-100)
ALT	32 U / L (reference 3-36)
Bilirubin	20 micromol / L (reference < 26)

Prolactin	469 mU / L (reference 80 - 400)
Luteinising hormone	0.9 IU / L (reference 1.8 - 8.6)
Follicle-stimulating hormone	1.2 mU / ml (reference 1.5 - 12.4)
Fasting LDL cholesterol	4.1 mmol / L (reference < 3.0)
Fasting HDL cholesterol	1.0 mmol / L (reference > 1.2)
HbA1C	45 mmol / mol (reference < 42)

What is the appropriate advice to the patient regarding the safe cessation of anabolic steroid use?

<input type="radio"/>	Convert patient to prescribed testosterone replacement and taper over 1 year
<input type="radio"/>	Taper anabolic steroid use over period of 6 months
<input type="radio"/>	Stop immediately, tapered withdrawal not required
<input type="radio"/>	Taper anabolic steroid use over period of 6 weeks
<input type="radio"/>	Convert patient to prescribed testosterone replacement and continue lifelong

Question 2 of 191

□ □

A 47-year-old builder presented with paraesthesia in both hands which was worse at night. His hands felt swollen, although they were not painful, and he had needed to buy a larger pair of work gloves. When at work he found that his hands felt weak. Over the past six months he had been experiencing urinary frequency, fatigue and increased thirst.

He had a past medical history of obesity and hypertension and his brother had type II diabetes mellitus. His only medication was ramipril. He was a heavy smoker with a 20 pack year history.

On examination of the arms there was weakness of thumb abduction bilaterally and diminished sensation over the radial three and a half digits. Percussion over the palmar aspect of the wrist reproduced the paraesthesia he described on presentation. On examination of the chest and abdomen there were areas of pigmentation in both axillae and striae over the abdomen. He had a protruberent abdomen and an elevated body mass index (BMI).

Which of the following investigations is most likely to be diagnostic?

	Magnetic Resonance Imaging of the Pituitary and visual field testing
	Fasting glucose on three occasions, glycosylated haemoglobin (HbA1c) and a 9am cortisol measurement
	Growth hormone measurement and dexamethasone suppression test
	Nerve conduction studies and electromyogram (EMG)
	Oral glucose tolerance test with serum glucose, IGF-1 and growth hormone measurements

Dashboard

Overall score: 0%

Question 3 of 191

□ □

A lady who is 10 weeks pregnant presents to her antenatal appointment asking for advice regarding gestational diabetes. She is a 31 year old English lady with a BMI (body mass index) of 28.7. In terms of family history she has a cousin who has type 1 diabetes mellitus and an aunt who is being treated for breast cancer. She has had two previous pregnancies, the first one she unfortunately miscarried at 8 weeks, and the second was a normal pregnancy that she took to term with a birth weight of 4.6kg. Neither of these pregnancies was complicated with gestational diabetes, and the baby is now 2 years old and has not had to be taken to see a doctor other than routine appointments.

What is the most appropriate testing regime for ruling out gestational diabetes in this woman?

	Oral glucose tolerance test at 24-28 weeks pregnant
	None - as she has no risk factors for gestational diabetes
	Oral glucose tolerance test at 12-14 weeks pregnant
	Self-monitoring of sugars and repeat appointment in 2 weeks
	HBa1c

□ Question 5 of 191

□ □

A 44-year-old woman is admitted to hospital complaining of a swollen breast for three days. She is otherwise well, having no medical problems. She is diagnosed by the surgical team with a breast abscess, which is drained and she is started on antibiotic treatment. Before being discharged, she is found to have elevated corrected calcium (2.79 mmol/L) and elevated parathyroid hormone (9.5 pmol/L).

She is reviewed by the endocrine team. She does not have any symptoms apart from those related to her breast abscess, and additional examination is unremarkable. Further tests are requested, showing that vitamin D levels are normal, 24-hour urine calcium is normal, and a DEXA scan is normal as well. She is advised to see her GP for annual blood tests for calcium levels and renal function.

She is diagnosed with primary hyperparathyroidism. What additional investigation should be used to monitor her?

	24-hour urine calcium annually
	Breast ultrasound annually
	Abdominal X-ray annually
	Abdominal ultrasound every three years
	DEXA scan every one to two years

She is reviewed by the endocrine team. She does not have any symptoms apart from those related to her breast abscess, and additional examination is unremarkable. Further tests are requested, showing that vitamin D levels are normal, 24-hour urine calcium is normal, and a DEXA scan is normal as well. She is advised to see her GP for annual blood tests for calcium levels and renal function.

She is diagnosed with primary hyperparathyroidism. What additional investigation should be used to monitor her?

	24-hour urine calcium annually
	Breast ultrasound annually
	Abdominal X-ray annually
	Abdominal ultrasound every three years
	DEXA scan every one to two years

Dashboard

□ Question 5 of 191

□ □

A 44-year-old woman is admitted to hospital complaining of a swollen breast for three days. She is otherwise well, having no medical problems. She is diagnosed by the surgical team with a breast abscess, which is drained and she is started on antibiotic treatment. Before being discharged, she is found to have elevated corrected calcium (2.79 mmol/L) and elevated parathyroid hormone (9.5 pmol/L).

She is reviewed by the endocrine team. She does not have any symptoms apart from those related to her breast abscess, and additional examination is unremarkable. Further tests are requested, showing that vitamin D levels are normal, 24-hour urine calcium is normal, and a DEXA scan is normal as well. She is advised to see her GP for annual blood tests for calcium levels and renal function.

□ Question 6 of 191

You are asked to review a 42- year- old alcoholic who has been admitted to the medical ward following 48hrs of vomiting, generalised muscle weakness and palpitations. Despite two calcium infusions, the most recent measured calcium is still 1.89 mmol/l. On examination his blood pressure is 95/60 mmHg, pulse is 95 beats per minute and regular. You note intermittent runs of SVT on his cardiac monitor.

Other urea and electrolytes are shown below:

Na ⁺ 132	mmol/l
K ⁺ 3.7	mmol/l
Urea 5.4	mmol/l
Creatinine 82	μmol/l
Glucose 5.2	mmol/l

Which of the following is the most appropriate next step?

	IV calcium
	IV magnesium
	IV potassium
	IV phosphate
	IV glucose

□ Question 6 of 191

Question 7 of 191

A 52 year-old woman presents with a two day history of nausea and fever. On admission she is confused and her husband states that she was recovering from a recent upper respiratory tract infection and sore throat. He also mentions she has previously been experiencing episodes of diarrhoea and palpitations over the last three months.

Examination reveals a temperature of 40.6°C, pulse rate of 160 beats per minute and blood pressure of 110/70 mmHg. Her pulse is irregularly irregular. Heart sounds 1 and 2 are present with no added sounds, lung fields are clear and her abdomen is soft and none tender, with bowel sounds being present.

Blood tests are taken and reveal:

Hb	13.2 g/dL
Platelets	180 * 10 ⁹ /l
WBC	10.2 * 10 ⁹ /l
Na ⁺	135 mmol/l
K ⁺	4.2 mmol/l
Urea	7.2 mmol/l
Creatinine	132 µmol/l
Thyroid stimulating hormone (TSH)	0.03 mu/l
Free thyroxine (T4)	31 pmol/l
Total thyroxine (T4)	220 nmol/l

What is the most appropriate immediate treatment?

	Carbimazole, corticosteroids and propranolol
	Carbimazole and propranolol

	Radio-iodine, corticosteroids and propranolol
	Carbimazole and corticosteroids
	Propylthiouracil, propranolol and carbimazole

□ Question 8 of 191

A 49-year-old man was brought in by ambulance after he had a prolonged tonic-clonic seizure for 45 minutes. He had no previous history of seizures, and this episode was witnessed by people passing by, who claimed he was jerking throughout his body and wet himself during the course of the fit. On admission, he was postictal after. His seizures stopped after administration of rectal diazepam, phenytoin infusion and intubation, and he was admitted to the intensive care unit. He remained drowsy and lethargic for the next 2 days, and attempts to wean him off the ventilator was slow.

His blood results on day 2 showed:

Na ⁺	140 mmol/l
K ⁺	5.8 mmol/l
Urea	11.1 mmol/l
Creatinine	180 µmol/l
Serum corrected calcium	2.15 mmol/l
Serum bilirubin	21 µmol/l
Serum alkaline phosphatase	97 IU/l
Serum aspartate aminotransferase	62 IU/l
Creatine kinase (CK)	9000 IU/l
Serum lactate	4.5 mmol/l
C-Reactive protein (CRP)	5 mg/l
Haemoglobin	13.6 g/dl
White cell count	7.2 x 10 ⁹ /L
INR	1.0

Which of the following values would likely be seen on his arterial blood gas result?

	pH 7.25 pO2 16 kPa pCO2 4.6 kPa HCO3 11mmol/l BE -10mmol/l, Cl- 101mmol/l
	pH 7.46 pO2 16 kPa pCO2 2.4 kPa HCO3 31mmol/l BE 5mmol/l, Cl- 101mmol/l
	pH 7.29 pO2 15 kPa pCO2 6.6 kPa HCO3 36mmol/l BE 6mmol/l Cl- 111mmol/l
	pH 7.48 pO2 17 kPa pCO2 6.4 kPa HCO3 11mmol/l BE -10mmol/l, Cl- 101mmol/l
	pH 7.36 pO2 17 kPa pCO2 4.6 kPa HCO3 27mmol/l BE -2mmol/l , Cl- 101mmol/l

□ Question 9 of 191

A 19-year-old woman comes to the endocrine clinic for review. She has problems with hirsutism and irregular periods, and troublesome weight gain. Her GP has just stressed the need to lose weight and offered no pharmacological intervention. She takes no medication from the doctor and is currently studying law. Examination reveals a blood pressure of 135/85 mmHg, pulse is 65 beats per minute and regular. body mass index is 32kg/m². You confirm extensive hirsutism affecting the beard line, upper lip and the nipples. there is acne over the face and the upper chest. Relevant bloods include:

testosterone	4.8 nmol/l (upper limit of normal 2.1 nmol/l)
LH:FSH ratio	2.1
fasting glucose	5.0 mmol/l

Her main concern is hirsutism.

Which of the following is the most appropriate intervention?

	Co-cyprindiol
	Clomiphene
	Levonorgestrel
	Metformin
	Pioglitazone

Dashboard

□ Question 10 of 191

A 45-year-old woman is admitted with hallucinations. She has a long history of alcohol dependency and is being treated by her GP for hypothyroidism. Further questioning of her husband reveals a 3-month history of diarrhoea, difficulty swallowing and an itchy rash on her arms. Prior to this she had been irritable and suffered from regular bouts of vomiting.

The examination is limited as the patient is aggressive . There is a pigmented, scaly rash on her arms and neck. Heart sounds are normal, her chest is clear and her abdomen soft. Neurological examination reveals generalised weakness.

Blood tests show:

Hb	142 g/l
Platelets	200 * 10 ⁹ /l
WBC	5.3 * 10 ⁹ /l

Na ⁺	140 mmol/l
K ⁺	4.2 mmol/l
Urea	6 mmol/l
Creatinine	84 µmol/l

TSH	4.0 U/mL
Free T3	3.1 pg/mL
Free T4	1.5 ng/L

What is the most likely diagnosis?

	Beriberi

	Thyroxine toxicity
	Systemic lupus erythematosus (SLE)
	Pellagra
	Darier's disease

Question 13 of 191

A 45-year-old gentleman presents to clinic for review. Two weeks ago he presented to the emergency department with renal colic. A spiral CT KUB confirmed nephrolithiasis and he was managed conservatively with IV fluids, analgesia and an alpha-blocker. His symptoms resolved entirely and he was discharged.

Blood tests:

Hb	142 g/l
Platelets	329 * 10 ⁹ /l
WBC	6.6 * 10 ⁹ /l
Na ⁺	141 mmol/l
K ⁺	3.8 mmol/l
Urea	6.2 mmol/l
Creatinine	71 µmol/l
Corrected calcium	2.71 mmol/l
Parathyroid hormone	10.2 pmol/l

Urine tests (24-hour collection):

Urinary calcium	183 mg
-----------------	--------

How should he be further managed?

	Annual monitoring of calcium and renal function
	Encourage oral fluids
	Bisphosphonates
	Vitamin D supplementation

	Parathyroidectomy
--	-------------------

Question 14 of 191

□ □

A 34 year old man is admitted under the medics from the emergency department with central abdominal pain and vomiting not responding to IV morphine. He had been seen by the surgeons earlier in the day as an acute abdomen, but the CT scan they did of his abdomen and pelvis revealed no abnormalities, and his bloods suggested no surgical cause of the abdominal pain.

You note that the patient has presented to the emergency department five times in the past two years with similar problems, and no cause has ever been found, with the patient being discharged one or two days later with analgesia.

On examination his abdomen is generally tender with evidence of voluntary guarding. On further examination you note that he has a rash on the back of his hands, neck and cheeks. This rash consists of several small fluid filled bullae.

His past medical history includes depression - for which he is taking citalopram, and one short psychiatric inpatient stay for an episode of psychosis.

What is the most likely diagnosis?

	Erythropoietic protoporphyria
	Porphyria cutanea tarda
	Hereditary coproporphyria
	Acute intermittent porphyria
	Congenital erythropoietic porphyria

Question 15 of 191

□ □

A surgical Foundation Year 1 doctor (FY1) asks you to review a preoperative ECG for a 19-year-old patient who has been admitted under their team with suspected appendicitis. The only abnormality is a prolonged QT and you note the adjusted calcium to be 2.02 mmol/l.

The FY1 tells you that when they looked at the patient's closed fists the outer two knuckles looked like dimples. She also tells you that the patient's body mass index is 29 kg/m².

You ask her to order some blood tests which come back as follows:

Adjusted calcium	2.02 mmol/l
PTH	69 pmol/L (normal range = 0.8 - 8.5)
Phosphate	2.0 mmol/l
ALP	130 u/l

What is the most likely underlying cause for this patient's hypocalcaemia?

	Hypoparathyroidism
	Pseudohypoparathyroidism type 1a
	Pseudohypoparathyroidism type 1b
	Pseudopseudohypoparathyroidism
	Secondary hyperparathyroidism

Question 15 of 191

□ □

A surgical Foundation Year 1 doctor (FY1) asks you to review a preoperative ECG for a 19-year-old patient who has been admitted under their team with suspected appendicitis. The only abnormality is a prolonged QT and you note the adjusted calcium to be 2.02 mmol/l.

The FY1 tells you that when they looked at the patient's closed fists the outer two knuckles looked like dimples. She also tells you that the patient's body mass index is 29 kg/m².

You ask her to order some blood tests which come back as follows:

Adjusted calcium	2.02 mmol/l
PTH	69 pmol/L (normal range = 0.8 - 8.5)
Phosphate	2.0 mmol/l
ALP	130 u/l

What is the most likely underlying cause for this patient's hypocalcaemia?

	Hypoparathyroidism
	Pseudohypoparathyroidism type 1a
	Pseudohypoparathyroidism type 1b
	Pseudopseudohypoparathyroidism
	Secondary hyperparathyroidism

□ Question 16 of 191

A 32-year-old female presents to the infertility clinic with an inability to conceive. She is overweight, with a body-mass index of 32 kg/m², and has noticed increased hair growth over her face and chest over the last 12 months. Her periods are irregular and she has also noticed a deepening of her voice. An ultrasound of the pelvis has revealed the presence of multiple cysts in both ovaries. She has been treated with cyproterone acetate for her hirsutism but was informed that she should not attempt conception whilst on the drug. She now wishes to conceive.

On examination, she has a cushingoid appearance, with abdominal striae and her blood pressure is 140/85 mmHg.

Laboratory investigations reveal:

9:00 am Cortisol	710 nmol/l (170 700 nmol/l)
LH	28 iU/l (1 20 iU/l)
Basal FSH	4.7 iU/l (1.0 8.8 iU/l)
DHEAS	509 µg/dl (31 228 µg/dl)
Prolactin	602 mU/l (<360 mU/l)
17 OH Progesterone	54 ng/dl (<80 ng/dl)

Which of the following treatment options would be most appropriate for the treatment of infertility?

	Metformin
	Spironolactone
	Reverse circadian rhythm steroids
	Clomiphene citrate
	Cabergoline

□ Question 16 of 191

	Cabergoline

□ Question 17 of 191

□ □

A 34-year-old woman is reviewed in clinic. She has been suffering from increasing tiredness for the last three months. She has no other symptoms and specifically denies pain, bleeding, weight loss and mood problems. She has a past medical history of asthma but has not needed her blue inhaler in over a year. She has no allergies. Her only regular medication is the oral contraceptive pill. Blood tests show a normal FBC, U&Es, calcium, parathyroid hormone but low vitamin D (32 nmol/L). What is the most appropriate treatment in regards to her low vitamin D?

	Dietary advise only
	Loading dose vitamin D
	Maintenance dose vitamin D
	Combined calcium and vitamin D
	No treatment needed

□ Question 18 of 191

A 56-year-old man with a history of type 2 diabetes managed with Humalog mix 30 and metformin 1g BD comes to the clinic for review. HbA1c is currently 57. He has troublesome hypoglycaemia episodes in the late afternoon and early mornings and wants to know what to do about it. On examination his blood pressure is 132/82 mmHg, his pulse is 72 beats per minute and regular. His body mass index is 32 kg/m².

Investigations

Na ⁺	139 mmol/l
K ⁺	4.9 mmol/l
Urea	5.1 mmol/l
Creatinine	94 µmol/l
HbA1c	57 mmol/mol

Which of the following is the most appropriate next step in his management?

	Continue current regimen, eat a snack mid afternoon and before bed time
	Reduce the dose of metformin
	Reduce the dose of mixed insulin
	Switch to a basal bolus regimen
	Switch to Humalog mix 20

□ □

A 64-year-old man is reviewed in clinic. He has a history of ischaemic heart disease and was diagnosed with type 2 diabetes mellitus around 12 months ago. At this time of diagnosis his HbA1c was 7.6% (60 mmol/mol) and he was started on metformin which was titrated up to a dose of 1g bd. The most recent bloods show a HbA1c of 6.8% (51 mmol/mol). He has just retired from working in the IT industry and his body mass index (BMI) today is 28 kg/m². His other medication is as follows:

Atorvastatin 80mg on
Aspirin 75mg od
Bisoprolol 2.5 mg od
Ramipril 5mg od

What is the most appropriate next step?

	Add sitagliptin
	Make no changes to his medication
	Add glimepiride
	Add pioglitazone
	Add exenatide

□ Question 21 of 191

You are seeing a 50-year-old lady with type 2 diabetes mellitus in the outpatient clinic. She has a past medical history of gastritis, moderate left ventricular dysfunction and chronic obstructive pulmonary disease. She is currently on metformin and gliclazide. Since last review she has gained 5kg in weight and her HbA1c has deteriorated to 70 mmol/mol from 62 mmol/mol. Body mass index today in clinic is 33 kg/m².

Recent blood tests are as follows:

Na ⁺	141 mmol/l
K ⁺	3.9 mmol/l
Urea	6 mmol/l
Creatinine	140 µmol/l

She was unable to previously tolerate liraglutide due to nausea and vomiting. What would be the best alteration to her therapy?

	Empagliflozin (SGLT-2 inhibitor)
	Add insulin
	Add pioglitazone
	Increase dose of metformin
	Increase dose of gliclazide

Dashboard

Overall score: 0%

Question 22 of 191

□ □

A 45-year-old man presents to the endocrine clinic for review. He has had 3 stones in weight gain over the past 6 months and his GP is concerned about a possible diagnosis of Cushing's syndrome and has checked an initial 24hr urinary free cortisol which is elevated. He is hypertensive with a blood pressure of 155/90 mmHg, his pulse is 75 beats per minute and regular. His body mass index is 35 kg/m² and there are obvious abdominal striae. Which of the following would be most suggestive of an adrenal adenoma producing cortisol?

	Normal 9am serum cortisol
	Raised urinary free cortisol on repeat testing
	Serum cortisol of 220 mmol/l at 9am after an overnight dexamethasone suppression test
	Serum potassium of 2.4 mmol/l
	Undetectable levels of ACTH

Dashboard

□ Question 23 of 191

A 58-year-old man is referred to metabolic medicine clinic by his urologist. The patient has been unfortunate enough to suffer from repeated episodes of renal stones over the past few years.

The initial presentation was of multiple attacks of right sided ureteric colic with presence of renal calculi demonstrated on ultrasound. At this initial presentation, the patient's stones had passed spontaneously. The patient reported that since his initial symptoms he had been very careful to maintain his hydration level, going so far as to carry a large water bottle with him at all times.

Two months previously, a new episode of left sided ureteric colic had started. Abdominal CT scanning had shown multiple left and right sided renal calculi with left sided hydronephrosis and hydroureter. The patient had undergone lithotripsy and an ureteric stent had been sited to relieve the obstruction. The stent had been removed after six weeks and a retained renal calculi sent to the laboratory for analysis.

The patient had an otherwise fairly limited past medical history, reporting only a previous diagnosis of hypercholesterolaemia and a previous appendicectomy. His only regular medication was simvastatin 40 mg daily. The patient lived with his wife and worked full time as a bus driver.

While the patient was currently free of symptoms, he was keen to consider any further interventions that would reduce his risk of suffering from recurrent attacks in the future. Results of investigations organised following clinic review are given below.

Urea	7.3 mmol / L
Creatinine	95 micromol / L
Sodium	137 mmol / L
Potassium	4.7 mmol / L
Parathyroid hormone	5.1 pmol/L (reference: 1.6-6.9)
Urinary calcium (24 hour collection)	11.6 mmol / 24 hours (reference: 2.5-8.6)
Urinary sodium (24 hour collection)	156 mmol / 24 hours (reference 40-220)
Urinary uric acid (24hour collection)	2.5 mmol / 24 hours (reference: < 4.8)

What is the correct management to reduce the patient's risk of recurrent renal stones?

	Chlorthalidone
	Allopurinol
	Acetohydroxamic acid
	Bumetanide
	Sodium bicarbonate

Dashboard

Overall score: **0%**

Question 24 of 191

□ □

You are asked to review a 67-year-old man who is currently an inpatient on a surgical ward with new paraesthesia in his fingers. He was admitted for an elective parathyroidectomy three days ago for fairly long standing hyperparathyroidism and subsequent hypercalcaemia. He had a single parathyroid adenoma excised which had been identified on pre-operative MIBI scanning. The procedure was without complications but he is now complaining of a tingling sensation in his fingers that he first noticed about twelve hours ago. He also complains of new severe pain in both of his ankles which is worse when he walks, but also present at rest. The surgical SHO has already arranged x-rays of the patient's ankles and these reveal multiple osteolytic lesions which have been reported as being suspicious for metastatic disease. He is otherwise fit and well and his only regular medications are paracetamol, tramadol and prophylactic dalteparin. His blood tests are as follows.

Adjusted Calcium	1.84 mmol/L
Magnesium	0.7 mmol/L

What is the most likely explanation for his current symptoms?

<input type="checkbox"/>	Metastatic parathyroid cancer
<input type="checkbox"/>	Secondary hyperparathyroidism
<input type="checkbox"/>	Hypomagnesaemia
<input type="checkbox"/>	Hungry bone syndrome
<input type="checkbox"/>	Secondary hypoparathyroidism

A 30-year-old south Asian woman is admitted to the accident and emergency department with abdominal pain. She is thought to be constipated. Initial blood results with subsequent tests are listed below. Urine is clear and an ECG performed is normal. Examination is unremarkable with no oedema, and blood pressure 105/68 mmHg.

pH	7.250
Bicarbonate	18.0 mmol/l
Base excess	8.0 mmol/l
Anion gap	Normal

Potassium	7.2 mmol/l
Creatinine	56 mmol/l
Glucose	5.3 mmol/l
Thyroid function	Normal
Aldosterone	Normal
Renin	Normal
Protein electrophoresis & immunoglobulins	Normal
Urinary sodium	94 mmol/l (normal range >20 mmol/L)
Urinary potassium	26.8 mmol/l (normal range >25 mmol/L)
17- hydroxyprogesterone	Normal
Short synacthin test (basal)	320 nmol/l
Short synacthin test (30 mins)	750 nmol/l

What is the likely diagnosis?

	Renal tubular acidosis type 1
	Renal tubular acidosis type 2
	Renal tubular acidosis type 4
	Gitelman syndrome
	Adrenal insufficiency

Question 27 of 191

A 30-year-old south Asian woman is admitted to the accident and emergency department with abdominal pain. She is thought to be constipated. Initial blood results with subsequent tests are listed below. Urine is clear and an ECG performed is normal. Examination is unremarkable with no oedema, and blood pressure 105/68 mmHg.

pH	7.250
Bicarbonate	18.0 mmol/l
Base excess	8.0 mmol/l
Anion gap	Normal

Potassium	7.2 mmol/l
Creatinine	56 mmol/l
Glucose	5.3 mmol/l
Thyroid function	Normal
Aldosterone	Normal
Renin	Normal
Protein electrophoresis & immunoglobulins	Normal
Urinary sodium	94 mmol/l (normal range >20 mmol/L)
Urinary potassium	26.8 mmol/l (normal range >25 mmol/L)
17- hydroxyprogesterone	Normal
Short synacthin test (basal)	320 nmol/l
Short synacthin test (30 mins)	750 nmol/l

What is the likely diagnosis?

	Renal tubular acidosis type 1
	Renal tubular acidosis type 2
	Renal tubular acidosis type 4
	Gitelman syndrome
	Adrenal insufficiency

Question 28 of 191

□ □

You are reviewing a 57 year-old gentleman in the diabetes outpatient clinic. He has type 2 diabetes mellitus and is currently taking metformin 850mg three times a day and gliclazide 80mg once daily.

On further questioning he admits having frequent hypoglycaemic episodes at night that distress him as he lives alone. His BMI is calculated at 30.3 kg/m², HbA1c 7.8% (62 mmol/mol) and his co-morbidities include congestive cardiac failure.

How would you change his diabetic treatment?

	Stop gliclazide, start insulin
	Add exenatide
	Add sitagliptin to current regimen
	Stop gliclazide, start pioglitazone
	Stop gliclazide, start sitagliptin

□ Question 29 of 191

45 year old female presents with a 2 year history of headache and visual blurring. When initially presenting to her GP 2 years ago, her blood pressure was found to be 235/160mmHg. Subsequently, despite maximal doses of four anti-hypertensives, including 50mg spironolactone, her blood pressure remains poorly controlled. Her latest blood tests demonstrate the following:

Na ⁺	140 mmol/l
K ⁺	2.9 mmol/l
Urea	5.8 mmol/l
Creatinine	78 µmol/l
CRP	2 mg/l

Serum ambulatory renin activity	0.34 pmol/L @ 3-4 hours (normal range 0.8-3.5 pmol/ml/hr)
Serum ambulatory aldosterone	2052 pmol/L@ 3-4 hours (normal range 100-800)

A CT adrenal reveal a right adrenal mass of 2.5cm diameter. The patient is keen to take away the underlying problem. What is the most appropriate next management step?

	Add amiloride
	Add eplerenone
	Increase spironolactone to 100mg OD
	Adrenal vein sampling
	Right adrenalectomy

Question 30 of 191

□ □

A 24-year-old nurse presents after collapsing on a night shift. His blood glucose is measured at being 1.4 mmol/l. His blood pressure at the time was noted to be 115/82 mmHg. He has no palpitations and had not bitten his tongue or become incontinent during the episodes. He was shaken afterwards, although did not have memory loss and stated he had not tripped over anything. He also said he has had five of these episodes over the last two weeks.

Blood tests are sent off and unremarkable except for a low-normal C-peptide level and markedly raised insulin level.

Which of the following is the most likely diagnosis of his multiple episodes of collapse?

	Sulphonylurea misuse
	Insulin misuse
	Alcohol misuse
	Retroperitoneal sarcoma
	Insulinoma

□ Question 31 of 191

A 34-year-old woman is referred to endocrinology clinic for assessment after reporting symptoms of heat intolerance, tremors and diarrhoea to her General Practitioner. Blood tests in primary care showed evidence of thyrotoxicosis. Further assessment at clinic revealed the symptoms had been present for approximately 4 weeks. The patient had initially attributed the symptoms to the stress of caring for her new baby, who had been born 6 weeks previously. She denied any symptoms of pain on eye movements, diplopia or skin rashes.

Past medical history included only her recent pregnancy with delivery by vaginal delivery. The patient took no regular medications. There was no family history of thyroid disorders. Prior to taking maternity leave, the patient worked as a lawyer. She did not drink or smoke.

Examination revealed a small, diffuse and mildly tender goitre with no evidence of thyroid bruit. There was fine tremor of outstretched hands but no exophthalmos or proptosis. Investigations requested following clinic review are listed below.

Thyroid stimulating hormone	0.1 microU / L (reference 0.4-5.0)
T4 free serum	19.5 pmol / L (reference 8.5-15.2)
T3 free serum	8.1 pmol / L (reference 3.5-6.5)
Thyroid peroxidase antibodies	250 mU / L (reference < 150)
Erythrocyte sedimentation rate	21 ml / h

Thyroid scintiscanning (Technitium-99): no significant thyroid uptake

What is the most likely diagnosis?

	Graves' disease
	Toxic thyroid nodule
	Viral thyroiditis
	Toxic multinodular goitre

	Post-partum thyroiditis

□ Question 32 of 191

A middle age woman is being treated for symptomatic hypercalcaemia associated with a squamous cell lung cancer (serum calcium 3.60 mmol/L). She is slow to respond to initial measures of saline hydration and intravenous pamidronate. Whilst awaiting surgical resection for her underlying cancer what may be the next best step in her management?

Na ⁺	142 mmol/l
K ⁺	4.3 mmol/l
Urea	7.0 mmol/l
Creatinine	89 µmol/l
Glucose	4.8 mmol/l

What is the most appropriate management?

	High dose loop diuretics
	Calcitonin 4 units/kg
	Insulin actrapid 50 units in 50% dextrose
	IV colloid administration instead of crystalloid
	Plasma exchange

Dashboard

□ Question 33 of 191

A 60-year-old man attends a medical health check-up at his GP surgery. He was fit and well with a past medical history of childhood asthma and osteoarthritis in his fingers. His observations were included a blood pressure of 129/80 mmHg, pulse of 82 bpm, and oxygen sats of 97%.

Blood tests were performed and revealed:

Hb	138 g/l	
Platelets	$190 \times 10^9/l$	
WBC	$7.6 \times 10^9/l$	
Na ⁺	139 mmol/l	
K ⁺	3.9 mmol/l	
Urea	4.1 mmol/l	
Creatinine	9.2 μ mol/l	
Bilirubin	15 μ mol/l	
ALP	52 u/l	
ALT	26 u/l	
γ GT	58 u/l	
Albumin	40 g/l	
Serum corrected calcium	2.77 mmol/L	
Serum phosphate	0.90 mmol/l	
Parathyroid hormone	5.9 pmol/L	normal range 1.2-5.8 pmol/L

A 24 hour urinary calcium test was performed based on the results above and revealed a result of 0.5 mmol/24 hours (normal range 2.4-7.4 mmol/24 hours)

What is the most likely diagnosis?

	Primary hyperparathyroidism
	Secondary hyperparathyroidism
	Vitamin D toxicity
	Multiple endocrine neoplasia type A
	Familial benign hypocalciuric hypercalcaemia

Question 34 of 191

A 32 year-old man is referred by his GP after collapsing while at work. He does not remember the episode but witnesses say that there was no incontinence or fitting and the patient does not have a sore mouth or tongue. This is the first time this has happened and the patient does not have any other past medical history of note and takes no regular medication.

Examination reveals a blood pressure of 162/95 mmHg, a pulse of 74 beats per minute, a respiratory rate of 16 and a temperature of 37.4°C. Heart sounds 1 and 2 are present with no added sounds, the lung fields are clear and his abdomen is soft and non-tender.

Blood tests performed and reveal:

Na ⁺	143 mmol/l
K ⁺	3.0 mmol/l
Urea	5.6 mmol/l
Creatinine	76 µmol/l
Bicarbonate	31 mmol/l
Renin	low
Aldosterone	low

Which of the following is the best treatment?

	Amiloride
	Bumetanide
	Spironolactone
	ACE inhibitor

	ACE inhibitor

□ Question 35 of 191

A 52-year-old lorry driver was referred to the secondary care diabetes mellitus by his GP with poorly controlled diabetes. He was diagnosed with type 2 diabetes mellitus six years ago. Unfortunately, he has not engaged with lifestyle interventions and his diabetes has been poorly controlled since diagnosis. He has since developed diabetic nephropathy and proliferative retinopathy. Other than diabetes he has a past medical history comprising of ischaemic heart disease, hypertension, hypercholesterolaemia, osteoarthritis and gout. At the point of referral he was prescribed aspirin 75mg OD, ramipril 10mg OD, simvastatin 40mg ON, naproxen 250mg BD, co-codamol 8/500 2tabs QDS, lansoprazole 30mg OD, metformin 500mg TDS, gliclazide 80mg BD and pioglitazone 30mg OD. He smoked 20 cigarettes per day and consumed 15 units of alcohol per week.

Examination revealed an obese gentleman with a BMI of 38 kg/m. His blood pressure was 148/88 mmHg. Cardiovascular examination revealed the presence of normal heart sounds and a JVP of 3cm. Examination of the respiratory, abdominal and neurological systems was unremarkable. Investigations reveal the following results:

Na ⁺	136 mmol/l
K ⁺	5.1 mmol/l
Urea	14.1 mmol/l
Creatinine	148 µmol/l
Total cholesterol	5.1 mmol/l
HDL cholesterol	1.3 mmol/l
HbA1c	68 mmol/mol (8.4%)

What is the next best step management step?

	Commence exenatide
	Commence sitagliptin
	Commence insulin glargine

	Increase dose of pioglitazone
	Commence orlistat

Dashboard

Overall score: **0%**

□ Question 39 of 191

You are asked to review a 43-year-old man in theatre recovery who has developed a fever and tachycardia post-operatively. He is previously fit and well, does not smoke and drinks alcohol only occasionally. He had fallen the previous night and suffered a distal radius fracture and has just undergone a open reduction and internal fixation under general anaesthetic. During anaesthesia he received 4mg ondansetron and 8mg dexamethasone for post-operative nausea and 10mg morphine for pain. He denies feeling unwell and has no symptoms suggestive of intercurrent infection.

On examination his heart rate is 130 beats/min and irregular, his blood pressure is 135/74 mmHg and his temperature is 39.4°C. His chest is clear to auscultation, his abdomen soft and non-tender and there is no rash or meningism. His right forearm is in plaster, but is not particularly painful and his fingers are warm and have normal sensation.

Hb	130 g/l
Platelets	460 * 10 ⁹ /l
WBC	10.5 * 10 ⁹ /l
Na ⁺	138 mmol/l
K ⁺	4.1 mmol/l
Urea	5.1 mmol/l
Creatinine	95 µmol/l
C-reactive protein	1 mg/L
Thyroid stimulating hormone	<0.02 mIU/L
Cortisol	45 µg/dL

What is the most appropriate initial treatment?

	Carbimazole
	Hydrocortisone

	Propranolol
	Broad spectrum antibiotics
	Crystalloid infusion

□ Question 40 of 191

A 31-year-old female presents with a 2-day history of abdominal pain, a 5-day history of diarrhoea and vomiting and reduced appetite. She is a known type one diabetic with background diabetic retinopathy and stage 3 chronic kidney disease. She usually takes 32 units lantus at night and variable doses of Novomix with meals however due to her poor appetite she has not taken these for 2 days. On examination, she looks unwell. The airway is patent and chest is clear. Respiratory rate is 26/min with normal oxygen saturations on air. Pulse is 120/min and thready with a capillary refill of 3 seconds centrally. Blood pressure is 103/45 mmHg with a temperature of 36.7°C. Abdomen is generally tender without guarding. Capillary blood glucose is 26 and ketones are 4.9. Arterial blood gas is as follows:

pH	7.32
pO ₂	11.6 kPa
pCO ₂	3.32 kPa
Bicarbonate	14 mmol/l
Base Excess	-6.5 mmol/l
Lactate	2.1 mmol/l

The patient is currently being fluid resuscitated appropriately. What form of insulin therapy would you advise?

	Dose of novomix now and increase usual lantus by 8 units
	Variable rate i.v insulin, continue all s/c insulins
	Recommence normal s/c insulin regimen
	Fixed rate i.v insulin, continue lantus
	Fixed rate i.v insulin, stop all s/c insulin

Question 41 of 191

□ □

A 55 year-old male presents to endocrine outpatient clinic for investigation of gynaecomastia. On examination he has bilateral growth of breast tissue with palpable glandular tissue around the areolae. His past medical history includes hypertension, hypothyroidism, and congestive cardiac failure. He drinks 30 units of alcohol per week. His regular medications include: levothyroxine, amlodipine, bisoprolol, lisinopril and spironolactone.

On examination he is of normal stature, there are no peripheral stigmata of chronic liver disease or testicular masses.

What is the most likely explanation of his gynaecomastia?

	Cirrhosis
	Hypopituitarism
	Iatrogenic
	Klinefelter's syndrome
	Idiopathic

Question 42 of 191

□ □

A 39 year-old man presents to his GP for an annual review of his type 1 diabetes. His main complaints over the last year are having several episodes of vomiting after meals and chronic constipation, as well as having loss of sensation on both of his legs up to his knees and some sensory loss in his fingertips. On further questioning, you establish there has been no weight loss or haematemesis. On examination, his HbA1c is 72 mmol/mol, blood pressure is 138/88 mmHg and his pulse is regular and 84 beats per minute. Neurological examination demonstrates a lack of proprioception up to the ankle joint and loss of sensation as described above.

What is the most appropriate symptomatic treatment for the gastrointestinal symptoms described above?

	Lansoprazole
	Omeprazole
	Metoclopramide
	Mirtazapine
	Cyclizine

 Question 43 of 191

A 23-year-old female presented with acne and hirsutism worsening over the last 3 years. She attained menarche aged 10 and has irregular periods.

On examination, body mass index 29kg/m², heart rate 80/min, blood pressure 135/85 mmHg. Hirsutism and acanthosis nigricans are noticed along with mild clitoromegaly.

Bloods on 6th day after menstruation:

Estradiol	300 pmol/L (early follicular NR<300 pmol/L)
17OH-progesterone	20 nmol/L (NR<10 nmol/L)
Free Testosterone	3 nmol/L (NR<3 nmol/L)
LH	4 IU/L (NR 1-9 IU/L)
FSH	3 IU/L (NR 1-13 IU/L)
9am cortisol	150 nmol/L (NR 200-700 nmol/L)

What is the single most useful test?

<input type="checkbox"/>	CT adrenals
<input type="checkbox"/>	Karyotype
<input type="checkbox"/>	Pelvic USS
<input type="checkbox"/>	Short synacthen test
<input type="checkbox"/>	MRI pituitary

Question 44 of 191

□ □

A 54-year-old gentleman is reviewed prior to discharge. He was admitted three days ago with an infective exacerbation of COPD requiring nebulisers and IV antibiotics but he did not need non-invasive ventilation or ITU admission. He has responded well to treatment and his wheeze is completely gone. His cough is also much improved. He has a background of type 2 diabetes mellitus, gout, diabetic retinopathy and hypertension. He raises concerns about his blood pressure as the nurses have told him it is persistently around 150mmHg systolic. He monitors blood pressure at home and normally his readings are much better. You reassure him that it is likely because his ramipril was held on admission. What should his blood pressure be less than during his next GP review?

	130/80mmHg
	135/85mmHg
	140/80mmHg
	140/90mmHg
	130/90mmHg

Key

A = ACE inhibitor

C = Calcium channel blocker

D = Thiazide Diuretic

□ Question 45 of 191

A 60 year old woman had a thyroid function test requested by her General Practitioner after reporting some symptoms of mild lethargy. This had unexpectedly demonstrated a suppressed Thyroid Stimulating Hormone level (0.25 microU / L) but normal free T4 level (14.1 pmol / L). During further consultation, the patient denied any heat intolerance, weight loss, diarrhoea, hair or skin changes, palpitations or eye symptoms.

The patient had had a hysterectomy without oophorectomy at age 45 as treatment for menorrhagia secondary to fibroids. She remember reaching menarche at around the age of 13 or 14 years. There was no significant family history of coronary artery disease. The patient reported her mother had suffered a fractured neck of femur at the age of 75 years following a fall. The patient was a retired school teacher with an active lifestyle. She had never smoked and drank very little alcohol.

Examination showed no evidence of a goitre, no fine tremor and no lid lag. External examination of the eyes was unremarkable. Cardiovascular and respiratory examination was unremarkable.

The GP requested some further basic investigations and then repeated blood tests 2 months after the original test. At this time, the patient reported her previous symptoms of lethargy had improved; with hindsight she attributed this to grief due to the recent death of a close friend.

Ambulatory blood pressure monitoring: average blood pressure 125 / 75 mmHg

ECG: sinus rhythm at 75 bpm; normal axis; no abnormality of QRS, ST interval or T waves.

Haemoglobin	12.8 g / dL
White cell count	6.5 x 10 ⁹ /l
Platelets	206 x 10 ⁹ /l
Urea	6.2 mmol / L
Creatinine	95 micromol / L
Sodium	137 mmol / L
Potassium	4.0 mmol / L

C-reactive protein	< 1
Parathyroid hormone	3.7 pmol / L (reference 1.2-5.8)
Thyroid-stimulating hormone	0.21 microU / L (reference 0.4-5.0)
T4 free serum	13.8 pmol / L (reference 8.5-15.2)
T3 free serum	5.6 pmol / L (reference 3.5-6.5)
HbA1C	5.6 % (reference 4-6)
Total cholesterol	4.0 mmol / L
LDL cholesterol	1.8 mmol / L
HDL cholesterol	1.9 mmol / L

What is the most appropriate management of the deranged thyroid function tests?

<input type="checkbox"/>	DEXA scan
<input type="checkbox"/>	Thyroid ultrasound
<input type="checkbox"/>	Start treatment with simvastatin
<input type="checkbox"/>	Radioiodine therapy
<input type="checkbox"/>	Treat with propylthiouracil

Question 46 of 191

□ □

A 67 year old woman with a known history of breast cancer with bony metastases is admitted to hospital unwell. She has confusion, headache, abdominal pain, generalised bony pain and significant nausea with vomiting.

Blood tests reveal:

Sodium	132mmol/L	Albumin	22mmol/L
Potassium	4.1mmol/L	Calcium (adj)	3.89mmol/L
Urea	19.2mmol/L	Phosphate	1.01mmol/L
Creatinine	191µmol/L	Magnesium	0.86mmol/L
ALP	212U/L		

She is aggressively fluid resuscitated with 0.9% sodium chloride 125ml/hour for 48 hours and given 90mg intravenous pamidronate.

Repeat blood tests demonstrate an improvement in the renal function but the adjusted calcium is still greater than 3.0mmol/L.

What is the next most suitable step in this patients management?

	Repeat infusion 90mg pamidronate
	200mg intravenous hydrocortisone four times daily
	100 units subcutaneous calcitonin three times daily
	250ng oral calcitriol single dose
	Refer to ITU to commence haemofiltration

Question 48 of 191

□ □

A 23-year-old woman attends a fertility clinic with her partner. She complains of oligomenorrhoea and galactorrhoea and has failed to get pregnant after 18 months of regular unprotected intercourse. Blood tests reveal a serum prolactin level of 6000 mIU/l (normal <500 mIU/l). A pituitary MRI is arranged which shows a microprolactinoma.

Which of the following is the best initial treatment?

	Octreotide
	Bromocriptine
	Trans-sphenoidal hypophysectomy
	Pituitary radiotherapy
	Transfrontal hypophysectomy

Question 49 of 191

□ □

A 29-year-old woman is referred by her GP to the outpatient department with increasing symptoms of heat intolerance, diarrhoea and anxiety over the past couple of weeks. The patient is 34 weeks pregnant with her first baby and has a past medical history of hyperthyroidism, currently being treated with 10mg carbimazole. She has no other past medical history of note and her mother also had hyperthyroidism. She does not smoke or drink alcohol and does not take any recreational drugs.

On examination, her pulse is 98 beats per minute, blood pressure is 124/82 mmHg and her respiratory rate is 14/min. Her oxygen saturation is 98% and temperature is 37.5°C.

Blood tests are performed and reveal:

Thyroid stimulating hormone (TSH)	0.04 mu/l
Free thyroxine (T4)	21 pmol/l
Total thyroxine (T4)	152 nmol/l

What is the most appropriate management?

	Refer patient for immediate caesarean section
	Increase carbimazole dose to 20mg once daily
	Commence radioiodine treatment
	Switch carbimazole to propylthiouracil
	Refer for a thyroidectomy

□ Question 54 of 191

A 30-year-old man was referred to endocrinology clinic for the assessment of the adverse consequences of anabolic steroid use. The patient reported that he had recently decided to stop using anabolic steroids, having been a regular user for the previous 5 years to support his body-building training. The patient cited the potential health risks of long-term anabolic steroid use as the reason behind his decision to cease his use.

The patient had followed a regime of an intramuscular injection of long-acting synthetic testosterone derivative every two weeks. The patient took a 4-week break from anabolic steroids every 12 weeks, in an attempt to limit the adverse side-effects. The patient denied ever having used oral or topical synthetic testosterone preparations and had always used sterile injecting equipment.

The patient stated that he had developed significant gynaecomastia and also suffered significant male pattern baldness since starting to use anabolic steroids. In addition, 2 years previously he had suffered a ruptured right biceps tendon while exercising, requiring a surgical repair and had a prolonged period of rehabilitation. There was no history of symptoms suggestive of cardiac or liver disease. The patient took no regular prescribed medications and reported an alcohol consumption of between 15 to 20 units per week.

General examination of the patient revealed a highly muscular and lean adult male. Moderate gynaecomastia was present, but there were no other signs of chronic liver disease. Examination of the cardiovascular and respiratory systems was unremarkable.

Please see below for the available results of blood tests taken prior to the patient's attendance at the clinic.

HbA1C	47 mmol / mol (reference < 42)
Total cholesterol	6.1 mmol / L (reference < 5.0)
Fasting LDL cholesterol	5.0 mmol / L (reference < 3.0)
Fasting HDL cholesterol	1.1 mmol / L (reference > 1.2)
Prolactin	490 mU / L (reference 80 - 400)
Luteinising hormone	<i>result pending</i>
Follicle-stimulating hormone	<i>result pending</i>

Testosterone	<i>result pending</i>
Epitestosterone	<i>result pending</i>

What pattern of results for the pending blood tests is consistent with the patient's anabolic steroid use?

	Elevated testosterone:epitestosterone ratio; normal luteinising hormone; normal follicle-stimulating hormone
	Suppressed testosterone:epitestosterone ratio; elevated luteinising hormone; suppressed follicle-stimulating hormone
	Suppressed testosterone:epitestosterone ratio; suppressed luteinising hormone; suppressed follicle-stimulating hormone
	Elevated testosterone:epitestosterone ratio; suppressed luteinising hormone; suppressed follicle-stimulating hormone
	Normal testosterone:epitestosterone ratio; elevated luteinising hormone; elevated follicle-stimulating hormone

□ Question 58 of 191

A 20-year-old female presented to the accident and emergency department with severe abdominal pain, vomiting and lethargy. On further questioning she stated that she had been generally unwell for the last four months during which time she lost 10 Kg in weight and had been tired all the time.

Last month she has been diagnosed with hypothyroidism and was prescribed levothyroxine 50 mcg daily.

Her mother and sister have hypothyroidism and take thyroxine. On examination, she looks unwell and dehydrated.

Her pulse is 105 beats per minute and blood pressure is 70/40 mmHg

Her temperature is 37.6°C and BMI is 19 kg/m². Cardiovascular, respiratory and abdominal examination were normal. Investigations done last month showed:

Hb	9.5 g/dl
MCV	105 fl
Platelets	190 * 10 ⁹ /l
WBC	4.5 * 10 ⁹ /l

Serum free T4	8.5 pmol/l
Serum TSH	5.5 mU/l

While awaiting new investigations, what is the most appropriate immediate treatment for this patient?

	Intravenous glucose 10%
	Intravenous normal saline
	Intravenous normal saline and antibiotics

	Intravenous normal saline and hydrocortisone
	Intravenous thyroxine

Question 61 of 191

A 48-year-old man who was diagnosed with type 2 diabetes mellitus presents for review. During his annual review he was noted to have the following results:

Total cholesterol	5.3 mmol/l
HDL cholesterol	1.0 mmol/l
LDL cholesterol	3.1 mmol/l
Triglyceride	1.7 mmol/l
HbA1c	6.4%

A QRISK2 score is calculated showing that he has a 12% 10-year risk of developing cardiovascular disease. His current medication is metformin 500mg tds. According to recent NICE guidelines, what is the most appropriate action?

	Simvastatin 40mg on
	Lifestyle advice, repeat lipid profile in 3 months
	Atorvastatin 40mg on
	Atorvastatin 20mg on
	Increase his metformin slowly to 1g tds

Question 61 of 191

A 48-year-old man who was
was noted to have the follow

Total cholesterol	5.3 mmol/L
HDL cholesterol	1.0 mmol/L
LDL cholesterol	3.1 mmol/L
Triglyceride	1.7 mmol/L
HbA1c	6.4%

A QRISK2 score is calculated as 10.5%. His current
medication is metformin 500mg tds. According to recent NICE guidelines, what is the most appropriate action?

	Simvastatin 40mg on
	Lifestyle advice, repeat lipid profile in 3 months
	Atorvastatin 40mg on
	Atorvastatin 20mg on
	Increase his metformin slowly to 1g tds

Primary prevention

(10-year cardiovascular risk $\geq 10\%$ OR
most type 1 diabetics OR
CKD if eGFR $< 60\text{ml/min/m}^2$)

(kn

Atorvastatin 20mg od

(if non-HDL has not fallen by $\geq 40\%$ then
consider titrating up to 80mg)

Question 62 of 191

□ □

A 42-year-old woman was seen in clinic with a history of palpitation, tremor and weight loss. There is no other past medical history and she takes no regular medication.

On examination, she had a palpable goitre, exophthalmos, and a tremor of the out-stretched hands.

Thyroid function tests showed:

Free thyroxine (T4)	36 pmol/L (10-25)
Free triiodothyronine (T3)	15 pmol/L (5-10)
Thyroid-stimulating hormone	0.1mU/L (0.4-5.0)

Which of the following treatments should be prescribed initially to improve symptoms?

	Thyroidectomy
	Propanolol
	Radioiodine ablation
	Carbimazole
	Propylthiouracil

Question 63 of 191

A 19-year-old pharmacy student is admitted to hospital after collapsing while at work. She denies biting her tongue or becoming incontinent during the collapse and was groggy but alert on coming around. At the time, a first aider measured her blood glucose to be 1.5 mmol/l. The patients mother reports that the patient has had 2 other episodes of collapse.

The students observations include a blood pressure of 127/77 mmHg, pulse of 81 bpm, and oxygen sats of 97%.

What is the best first-line investigation?

	Glucose, c-peptide and insulin
	Morning c-peptide
	Evening c-peptide
	Computed tomography (CT) scan of the abdomen
	Oral glucose tolerance test

Dashboard

Overall score: 0%

□ Question 64 of 191

A 75-year-old man with a history of high blood pressure, type 2 diabetes and hypercholesterolaemia was admitted to the emergency department with confusion. His daughter states that this has come on slowly over the last week and prior to this he had no memory problems. He currently takes metformin, ramipril, amlodipine and atorvastatin.

On examination, he smells strongly of urine and his mucous membranes appear dry. His abbreviated mental test score is 7 out of 10 and he is oriented in person but not in place or time. His heart rate is 95 per minute and his blood pressure is 105/62 mmHg. His chest is clear and has a soft ejection systolic murmur which does not radiate. His jugular venous pressure is not visible and he has mild ankle oedema. He has diffuse tenderness in the lower abdomen with no peritonism and normal bowel sounds. He has no focal neurology.

Investigation results are as follows:

Chest x-ray: Clear lung fields.

Urine dip:

Glucose	+++
Blood	+
Protein	+
Leucocytes	+
Nitrites	+
Ketones	+

Venous blood gas:

pH	7.43
BE	- 1.5 mmol/l
HCO ₃	23 mmol/l

Glucose	34 mmol/l
Lactate	2.5 mmol/l

Full blood count:

Hb	120 g/l
Platelets	445 * 10 ⁹ /l
WBC	13 * 10 ⁹ /l

Renal function:

Na ⁺	151 mmol/l
K ⁺	5 mmol/l
Urea	10 mmol/l
Creatinine	137 µmol/l
Glucose	32 mmol/l
Ketones	2 mmol/l

Which would be the most appropriate initial resuscitation measure?

	0.45% saline
	0.9% saline
	Fixed rate insulin and 0.9% saline
	Hartmann's
	Sliding scale insulin and 0.9% saline

Dashboard

□ Question 65 of 191

A 66-year-old male was admitted with agitation and confusion, worsening over the past 1 week. His past medical history includes hypertension, ischaemic heart disease and chronic back pain. His daughter noticed that he had lost about 1 stone in weight (currently weighs 71 kg), has been more tired over the last month and that he has been drinking a lot more water. This was associated with the development of urinary incontinence.

On examination, his heart rate was 108 beats/min, blood pressure was 95/42 mmHg, saturations were 94% on air and respiratory rate was 20/min. He is confused, with a Glasgow Coma Scale of 14 and appeared dehydrated.

Blood results are as follows:

Na ⁺	125 mmol/l
K ⁺	5.0 mmol/l
Urea	18 mmol/l
Creatinine	180 µmol/l
Blood glucose	34 mmol/l

Venous blood gas was done and showed the following:

pH	7.32
pCO ₂	4.6 kPa
pO ₂	6.1 kPa
HCO ₃	17mmol/l
BE	-3.6 mmol/l

Which is the most important treatment?

Intravenous 0.9% sodium chloride

	10 units of human actrapid stat
	Start insulin sliding scale at 6 units/hr
	Calcium gluconate
	Intravenous 1.8% sodium chloride

Dashboard

Overall score: **0%**

□ Question 66 of 191

A 37-year-old man attends endocrinology clinic for assessment of the unwanted effects of long-term anabolic steroid use. The patient had been a competitive bodybuilder, who had used anabolic steroids to enhance his training regime, but now stated that he had 'retired' from bodybuilding last week and so stopped using steroids. The patient was concerned about the long-term health consequences of his previous use.

The patient described a 10-year period of anabolic steroid use. Typically he would take a daily oral formulation of a synthetic testosterone supplemented by an intramuscular injection of a longer acting agent every few weeks. The patient would take breaks from anabolic steroid use intermittently throughout the year, to reduce unwanted effects and also to evade anti-doping testing arranged by the organisers of the competitions in which he competed. The patient stated that he had never shared or reused needles when injecting himself with anabolic steroids.

The patient reported a range of unwanted effects he had developed secondary to his anabolic steroid use. These included severe acne affecting the patient's face and chest, intermittent symptoms of gastrointestinal dysfunction, and male pattern baldness. When asked directly, the patient reported that he had suffered from erectile dysfunction and scrotal discomfort towards the end of his use of anabolic steroids. The patient did not report any other concerns, in particular, he denied symptoms associated with heart or liver disease. The patient had no other significant past medical history and disclosed being a former user of recreational drugs, including cocaine.

Examination of the patient's cardiovascular and respiratory symptoms was unremarkable except for moderate pitting oedema to the level of the mid-tibia bilaterally. Examination of the abdomen noted mild bilateral gynaecomastia but no other signs of chronic liver disease. The patient's testicular volume was estimated as 18 ml bilaterally. A brief mental state examination did not reveal any evidence of a significant mood or anxiety disorder.

HbA1C	47 mmol / mol (reference < 42)
Fasting LDL cholesterol	4.5 mmol / L (reference < 3.0)
Fasting HDL cholesterol	1.0 mmol / L (reference > 1.2)
Prolactin	501 mU / L (reference 80 - 400)
Luteinising hormone	1.4 IU / L (reference 1.8 - 8.6)
Follicle-stimulating hormone	1.2 mU / ml (reference 1.5 - 12.4)
Transthoracic	Normal systolic and diastolic function; no left ventricular hypertrophy; normal valvular

echocardiogram	function
----------------	----------

Which of the patient's unwanted effects will be irreversible with cessation of steroid use?

	Pitting oedema
	Erectile dysfunction
	Scrotal pain
	Male pattern baldness
	Gastrointestinal dysfunction

Dashboard

Overall score: **0%**

Question 67 of 191

A 32-year-old male presents with a sudden onset left sided weakness with new onset expressive dysphasia and dress apraxia. He has a seven year history of progressive cognitive impairment and seizures, lives in sheltered accommodation and was brought in after his relatives, who visit him on a weekly basis, noted a change from his baseline. The patient is a poor historian and could not remember the duration of symptoms. He reports a recent history of burning sensation when passing urine associated with increased frequency and reduced oral intake for the past four days. An MRI head demonstrates multiple areas of ischaemia within left and right cortex inconsistent with one single vascular territory. A urine dip is positive for leucocytes and nitrites, negative for ketones. A venous blood gas is taken:

pH	7.15
PaCO ₂	2.4 kPa
Bicarbonate	6 mmol/l
Lactate	18 mmol/l
Anion gap	16 mmol/l

What is the unifying diagnosis?

	MELAS
	Diabetic ketoacidosis
	Ingestion of antifreeze
	Severe dehydration secondary to urosepsis
	Metformin induced lactic acidosis

Question 68 of 191

□ □

A 52-year-old male presented with poor concentration, weight gain and tiredness for nine months duration. Three years ago he underwent resection of a pituitary tumour and was commenced on hydrocortisone 10 mg twice per day and thyroxine 150 g daily.

Examination reveals nothing significant.

Investigations show:

Serum free T4	12 pmol/L
Serum TSH	< 0.05 mU/L
Serum testosterone	7.3 nmol/L (10-30)
IGF-1	8.9 nmol/L (10-35)

What is the most appropriate treatment for this patient?

	Reduce the dose of thyroxine
	Reduce the dose of hydrocortisone
	Increase the dose of hydrocortisone
	Testosterone injection
	Growth hormone

Question 69 of 191

□ □

A 45-year-old woman with chronic alcohol abuse admitted 3 days ago for nausea and severe diarrhoea now complains of peri-oral and finger tingling. She was admitted for hydration after 1 week of severe watery diarrhoea. She has been receiving intravenous hydration and dextrose but has not been able to take oral nutrition secondary to continued nausea. Her blood pressure is 130/74 mmHg, pulse is 68/min, and respiratory rate is 16/min. She is afebrile.

Physical examination is significant for facial twitching on percussion of her facial nerve just anterior to the ear, as well as the induction of carpal spasm after the inflation of a blood pressure cuff on her arm.

Which of the following is most likely to have caused these findings?

	Hyperuricaemia
	Hypernatraemia
	Hypomagnesaemia
	Hypophosphataemia
	Hypouricaemia

Question 72 of 191

□ □

A 24 year-old man presents with a five week history of increasing thirst and frequency of urinating. The GP suspects diabetes and performs two fasting blood tests on separate days which reveal blood glucose results of 8.7 mmol/l and 9.2 mmol/l. Urinalysis does not detect any ketones or protein in the urine. The patient's mother had a diagnosis as type 1 diabetes at the age of 22 and his maternal grandfather and aunt also have type 1 diabetes. Due to the family history, the patient's c-peptide is measured and found to be consistently high on two occasions.

Given the likely diagnosis, what is the most appropriate first treatment for managing this condition?

	Gliclazide
	Metformin
	Pioglitazone
	Insulin
	Sitagliptin

Dashboard

Overall score: 0%

The patient's mother had a diagnosis as type 1 diabetes at the age of 22 and his maternal grandfather and aunt also have type 1 diabetes. Due to the family history, the patient's c-peptide is measured and found to be consistently high on two occasions.

Given the likely diagnosis, what is the most appropriate first treatment for managing this condition?

	Gliclazide
	Metformin
	Pioglitazone
	Insulin
	Sitagliptin

Question 73 of 191

A 55-year-old male presented to his general practitioner with a 4-month history of sweating, fatigue and daytime tiredness. He attributed his tight rings to 'fluid retention' and has been experiencing worsening headaches and deterioration in his vision.

He was diagnosed with acromegaly and underwent surgery for this condition 1 month ago. He has been feeling well since and has not experienced any new symptoms.

Which of the following investigations would be most useful for monitoring the effect of his therapy?

	MRI pituitary
	Echocardiography
	Growth hormone levels
	Insulin-like growth factor levels
	Oral glucose tolerance test

□ Question 74 of 191

A 33-year-old female is brought into the emergency department as a stand-by. She has felt unwell for the past 2 weeks. She describes lethargy, light-headedness and occasional shortness of breath. More recently she developed urinary frequency and dysuria. She received a domiciliary visit from her general practitioner 2 days ago and was prescribed trimethoprim for a possible urinary tract infection.

On arrival, she appears pale and clammy. Her peripheries are cold. Her observations reveal oxygen saturations of 94% on air, respiratory rate 28/min, heart rate 117/min, blood pressure 65/30 mmHg.

She has a past medical history of type 1 diabetes, uterine fibroids and hypothyroidism.

Initial investigations reveal:

White cell count	17.8 *10 ⁹ /l
Haemoglobin	97 g/l
Mean cell volume (MCV)	103.7 fL
Sodium	134 mmol/l
Potassium	4.9 mmol/l
Urea	7.0 mmol/l
Creatinine	120 µmol/l
Bilirubin	45 µmol/l
Alanine transaminase (ALT)	1051 U/l
Albumin	16 g/l
C-reactive protein (CRP)	71 mg/dL
Glucose	9.1 mmol/l

Urinalysis: ++protein, ++blood, +++leukocytes, ++nitrites, trace ketones

She is given intravenous fluids. Her blood pressure is 82/45 mmHg after a total of 3 litres of fluids. She is started on intravenous amoxicillin and gentamicin.

What is the next step in her management?

	1000mls intravenous colloid fluid
	Intravenous hydrocortisone
	Intravenous noradrenaline
	Intravenous albumin
	Intravenous meropenem

□ Question 76 of 191

□ □

A 22 year old lady presents over a year with mild-moderate, intermittent abdominal pain. She has felt low in mood over this period and also her periods have stopped. Her history includes two previous attacks of renal calculi formation managed conservatively. She had a car crash recently, where she says that the car just 'came out of nowhere'. She is intermittently getting global headaches that can be very severe in nature but are otherwise featureless. On prompting, she tells you that she has sometimes noticed a white nipple discharge on her clothing. She has had low blood pressure and several faints over this last year and after her GP discovered a low serum cortisol level he has started her on oral hydrocortisone and referred her to your clinic. On examination today her blood pressure 130/80. She has a blistering, red rash across her lower abdomen and back. Her abdomen is largely non-tender with no palpable organomegally or peritonism. Visual fields are reduced bitemporally. Her urine dipstick shows glycosuria. The remainder of the examination is unremarkable. Which of the following is likely to treat the underlying condition most effectively?

	Bisphosphonates
	Surgery
	Cabergoline
	Octreotide
	Insulin

Question 77 of 191

A 53 year old gentleman attends his General Practitioner for a 'Well Man Check'. He has a past medical history of hypertension which has been treated with ramipril for 4 years. As part of the screening the GP notes that the patient has been suffering from low back pain for the last couple of months. He has been taking paracetamol and ibuprofen that he has bought over the counter and this has eased his pain. His blood pressure today is 134/76 mmHg. His GP takes blood tests as part of the check and the results are shown below.

Hb	13.2 g/dl
Platelets	$312 \times 10^9/l$
WBC	$8.2 \times 10^9/l$

Na ⁺	138 mmol/l
K ⁺	6.6 mmol/l
Urea	6.2 mmol/l
Creatinine	114 μ mol/l

His GP notifies the patient immediately on seeing these results and refers him to the local Medical Assessment Unit. Where more tests are carried out.

Arterial Blood Gases:

pH 7.34
PaCO₂ 5.1kPa
PaO₂ 12kPa
HCO₃⁻ 20 mmol/l

Serum Chloride 120mmol/l

Urinalysis:

pH 4.8

Protein negative

Blood negative

Leukocytes negative

Glucose negative

What is the most likely diagnosis?

	Renal Tubular Acidosis type 1
	Renal Tubular Acidosis type 2
	Renal Tubular Acidosis type 3
	Renal Tubular Acidosis type 4
	NSAID induced nephropathy

□ Question 78 of 191

A 19-year-old woman presents to her GP with a 7 month history of weight loss, diarrhoea and palpitations. The diarrhoea is normal colour and over the last three months she has had roughly 2-3 bowel motions per day. The heart palpitations occur randomly throughout the day and night. She has also noticed that she has recently been getting episodes of feeling very hot and sweaty. She has no other past medical history and her only family history is a mother who has Hashimotos thyroiditis.

On examination, the patient is sweaty and her blood pressure is 130/80 mmHg, pulse is 102 bpm and regular, respiratory rate is 16/min and her oxygen SATs are 98% on air.

Blood tests are performed and reveal:

Hb	135 g/l
Platelets	220 * 10 ⁹ /l
WBC	7.1 * 10 ⁹ /l
Na ⁺	139 mmol/l
K ⁺	3.9 mmol/l
Urea	5.1 mmol/l
Creatinine	60 µmol/l
Free thyroxine (T4)	28 pmol/l
Thyroid stimulating hormone (TSH)	0.08 mu/l

A thyroid radioisotope scan is performed and reveals a globally reduced uptake.

What is the most likely diagnosis?

	Graves disease

	Thyrotoxicosis factitia
	Hashimotos disease
	De Quervains thyroiditis
	Atrophic thyroiditis

Question 79 of 191

A 29-year-old female is admitted to the Emergency Department following an episode of collapse. She denies prodromal symptoms and woke up after an undetermined period to find herself lying face down on the ground. She has recently consulted her GP regarding feelings of generalised weakness, intermittent palpitations and dizziness.

Her past medical history is remarkable for hypothyroidism and rheumatoid arthritis, previously managed with infliximab, and complicated 3 months ago by a diagnosis of TB. Her regular medications include methotrexate, folic acid, levothyroxine, artificial tears, rifampicin, and isoniazid.

During the examination, the patient complains of recurrent palpitations. The cardiac monitor shows broad-complex tachycardia. Her blood pressure is stable at 117/68mmHg and she is given a bolus of amiodarone.

Her venous blood gas is as follows:

pH	7.31
pCO ₂	4.3 kPa
pO ₂	6.3 kPa
Na ⁺	137 mmol/l
K ⁺	2.1 mmol/l
Cl ⁻	114 mmol/l
iCa ²⁺	1.05 mmol/l
Glucose	5.4 mmol/l
HCO ₃ ⁻	15.6 mmol/l
BE	-9.5 mmol/l

Some additional investigations are requested:

Urine dipstick	pH 5.0 glucose ++ protein +
----------------	-----------------------------

XR chest	unremarkable
XR abdomen	normal bowel gas pattern, no evidence of abnormal renal calcification

What is the most likely cause of the metabolic abnormalities described?

	Addison's disease
	Fanconi syndrome
	Rheumatoid arthritis
	Sjogren's syndrome
	Liver cirrhosis

Dashboard

Metformin not tolerated or CI

Question 81 of 191

A 53-year-old woman came six months ago after having been diagnosed with type 2 diabetes. She was started on metformin 500mg bd. What is the most appropriate next step in her management?

<input type="radio"/>	Reduce to metformin 250mg bd
<input type="radio"/>	Change to dipeptidyl peptidase-4 inhibitor
<input checked="" type="radio"/>	Trial of modified release insulin
<input type="radio"/>	Change to sulfonylurea
<input type="radio"/>	Change to pioglitazone

Primary prevention

(10-year cardiovascular risk $\geq 10\%$ OR
most type 1 diabetics OR
CKD if eGFR $< 60\text{ml/min/m}^2$)

Atorvastatin 20mg od

(if non-HDL has not fallen by $\geq 40\%$ then
consider titrating up to 80mg)

□ Question 82 of 191

You are asked to review a 55-year-old male surgical for the fourth time in seven days with persistent hyperkalaemia on his blood tests. He has been admitted for 5 weeks under the surgeons following AP resection of sigmoid carcinoma complicated by a superficial wound infection requiring a vacuum dressing. In all of the previous three medical reviews, the patient presented with a serum potassium of greater than 6.5 mmol/l and was treated with insulin-dextrose and calcium gluconate.

His past medical history includes type 2 diabetes mellitus, non-alcoholic steatohepatitis and neuromyelitis optica diagnosed 6 years ago and stable on the last review 2 months ago. His regular medications include gliclazide 80mg BD, Lantus (insulin glargine) 15 units OD, prednisolone 15 mg OD and baclofen 10mg QDS. During this review, he is alert and comfortable, blood pressure measures 135/82 mmHg, heart rate 90/min and sinus.

His blood tests are as follows:

Hb	121 g/l
Platelets	334 * 10 ⁹ /l
WBC	8.2 * 10 ⁹ /l

Na ⁺	136 mmol/l
K ⁺	6.9 mmol/l
Urea	7.5 mmol/l
Creatinine	110 µmol/l
CRP	4 mg/l
Renin	Raised
Aldosterone	Decreased

Blood gases show the following:

--	--

pH	7.24
PaO2 (air)	15.8 kPa
PaCO2	2.2 kPa
Bicarbonate	24 mmol/l

Urinary pH = 6.2

A repeat CT abdomen and pelvis demonstrates appropriate wounding healing with no local collections at the resection site. No other abdominal pathology is noted.

What is the most likely diagnosis?

<input type="radio"/>	Type 1 renal tubular acidosis
<input type="radio"/>	Type 2 renal tubular acidosis
<input type="radio"/>	Type 4 renal tubular acidosis
<input type="radio"/>	Waterhouse-Friderichsen syndrome
<input type="radio"/>	Addisonian crisis

□ Question 84 of 191

You are review a 38-year-old woman with type 1 diabetes mellitus in clinic. Her diabetes is currently controlled with a basal-bolus regime. She takes no other medication apart from citalopram 20mg od for depression. She was diagnosed with type 1 diabetes at the age of 13 years. Her most recent bloods show

Na ⁺	142 mmol/l
K ⁺	3.9 mmol/l
Urea	4.9 mmol/l
Creatinine	79 µmol/l

Total cholesterol	4.4 mmol/l
HDL cholesterol	1.2 mmol/l
LDL cholesterol	1.8 mmol/l
Triglyceride	1.3 mmol/l

Urine dip: No protein or blood

What is the most appropriate management with regards to lipid modification?

	Start atorvastatin 10mg on
	Start atorvastatin 20mg on
	Start atorvastatin 40mg on
	Perform a QRISK2 assessment
	Reassure her that lipid modification therapy is not required at this stage

□ Question 84 of 191

Question 85 of 191

□ □

A 24 year-old woman presents to hospital after collapsing while out shopping. On taking her observations, she has a temperature 37.2°C, a pulse rate of 78 per minute which is regular and normal in character and a blood pressure of 164/92 mmHg. Heart sounds 1 and 2 were present with no added sounds and his chest was clear on auscultation. His abdomen was soft and non-tender with no organomegaly. Neurological examination was unremarkable. She has no past medical history of note and is on no regular medications.

Further blood tests reveal low renin and aldosterone levels, hypokalaemia and a serum bicarbonate of 30 mmol/l.

Which of the following is the most appropriate treatment for her condition?

	Angiotensin converting enzyme inhibitor therapy
	Bumetanide
	Potassium replacement
	Spironolactone
	Amiloride

Question 86 of 191

A 56 year old male presents with progressive bilateral tinnitus of gradual onset over the past 3 months. He also reports worsening hearing during the same time period, intermittent headache and increasing lower limb oedema. He denies diplopia, vertiginous symptoms, dysphagia or dysarthria. He denies any urinary symptoms or weight loss. There is a past medical history of hypertension and insulin-dependent diabetes. The patient also reports a family history of prostate carcinoma, with both his father and uncle previously undergoing resections. On examination, cranial nerves are unremarkable except bilateral hearing loss. You note no limb weakness but significant spinal kyphosis. Heart sounds I and II are heard and no added sounds. Bibasal crackles are auscultated. His abdomen is soft and non-tender. His initial serum markers are as follow:

Platelets	264 * 10 ⁹ /l
WBC	9 * 10 ⁹ /l
Neuts	5.4 * 10 ⁹ /l

Na ⁺	142 mmol/l
K ⁺	4.3 mmol/l
Urea	7.8 mmol/l
Creatinine	90 µmol/l

Bilirubin	6 µmol/l
ALP	902 u/l
ALT	28 u/l
CRP	16 mg/l

Parathyroid hormone and vitamin D normal range. Which other biochemical marker will be abnormal?

	Corrected calcium
--	-------------------

	Gamma glutamyltransferase (GGT)
	Phosphate
	C-telopeptide (CTx)
	Prostate specific antigen (PSA)

Dashboard

Question 87 of 191

□ □

A 39-year-old woman is referred to the outpatient department by her GP having been unsuccessfully treated with trimethoprim and nitrofurantoin for recurrent urinary tract infections. These have been occurring over the past six months. Over the last 2 days, the patient reports that urinating has become very painful and that the patient is now having difficulty urinating. The patient has a past medical history of type 2 diabetes mellitus. After completing a course of amoxicillin, the patient still complains of pain on urinating and pain in the lower abdomen. There is a family history of type 2 diabetes mellitus and the patient has a smoking history of 5 pack years, while drinking on average 15 units per week. An HbA1c test is performed and reveals a result of 82 mmol/mol.

What is the most likely organism causing the recurrent urinary tract infections?

	Candida
	Neisseria gonorrhoea
	Chlamydia trachomatis
	Trichomonas vaginalis
	Mycoplasma genitalium

Investigations

Hb	102 g/l	Na ⁺	129 mmol/l
Platelets	189 * 10 ⁹ /l	K ⁺	5.0 mmol/l
WBC	10.9 * 10 ⁹ /l	Urea	9.9 mmol/l
Neuts	6.2 * 10 ⁹ /l	Creatinine	113 µmol/l
Lymphs	1.1 * 10 ⁹ /l	CRP	42 mg/l
Eosin	1.5 * 10 ⁹ /l		

Which of the following is the most important intervention with respect to her management?

	Fluid restriction
	IV anti-emetic
	IV hydrocortisone
	IV normal saline
	NG feeding

□ Question 90 of 191

□ □

A 72-year-old woman is recovering on the neurosurgical unit following a subdural haemorrhage. Four days earlier she underwent Burr hole surgery. You are asked to see her due to a persistently low sodium for the past three days. You note the following investigations:

Day 2 post-surgery

Serum Na ⁺	116 mmol/l
-----------------------	------------

Day 3 post-surgery

Serum Na ⁺	117 mmol/l
-----------------------	------------

Day 4 post-surgery

Serum Na ⁺	115 mmol/l
Urinary Na ⁺	25 mmol/l
Serum osmolality	280 mmol/l

Examination of the patient demonstrates dry mucous membranes and delayed capillary refill time.

What is the most likely diagnosis?

	SIADH
	Diabetes insipidus
	Cerebral salt wasting syndrome
	Renal tubular acidosis type IV
	Sheehan's syndrome

□ Question 91 of 191

□ □

A 28-year-old male with a history of epilepsy, for which he is taking carbamazepine and has not had any seizures for the last two years, presents with irritability and nausea for the last 2 weeks. His girlfriend says that he is often confused and seems to be lost most of the time. He takes alcohol occasionally and smokes ten to twelve cigarettes per day.

On examination, he is irritable but conscious and alert. Clinical examination revealed eczema over the face, shins and extensor surfaces of the forearms and a tattoo on the right shoulder. There was no evidence of any peripheral oedema.

Lab reports were as follows:

Hb	150 g/l
MCV	81 fl
MCH	31 pg
WBC	$9 \times 10^9/l$
Plt	$250 \times 10^9/l$
Urea	3.2 mmol/l
Creatinine	75 $\mu\text{mol/l}$
9:00 am Cortisol	345 nmol/l (170 700 nmol/l)
TSH	2.4 mU/l
Total T4	102 nmol/l (68 174 nmol/l)
Na+	119 mmol/l
K+	4.2 mmol/l

Which of the following would be the most appropriate initial management option?

	Fluid restriction to 500 - 1000 ml daily

	Demeclocycline 600 - 1200 mg daily
	IV hypertonic saline
	Intranasal desmopressin twice daily
	Hydrochlorothiazide 12.5 mg daily

Dashboard

□ Question 92 of 191

A 23-year-old Malaysian man presented to the emergency department with sudden onset right arm weakness that came on earlier in the morning after waking up. He denies any slurring of his speech. He has had one previous episode a month ago but that episode involved mild right leg weakness which resolved after 30 minutes, this time he is anxious as he was unable to move his arm and it has not resolved after 2 hours. His past medical history includes Grave's disease, and he takes carbimazole 20mg twice daily, however, he admits he has not been taking his carbimazole for the past week as he just returned from a month long holiday and had run out of medication.

On examination his temperature was 37.5°C, heart rate was 84 bpm, blood pressure was 114/68 mmHg, respiratory rate was 18 breaths per minute, and oxygen saturation was 98% on air. There was a fine tremor in both hands. Neurological examination revealed flaccid paralysis of the right arm, affecting the extensor muscles more than the flexor muscles (power 2/5 in the shoulder extensors). Reflexes and sensation to soft touch were normal. There was no disturbance of speech or facial asymmetry. There was a palpable smooth thyroid goitre in the midline of the neck.

C Reactive protein	6 mg/l
Haemoglobin	156 g/l
White cell count	$6.6 \times 10^9/L$
Na+	145 mmol/l
K+	3.1 mmol/l
Urea	5.2 mmol/l
Creatinine	78 $\mu\text{mol/l}$
Corrected calcium	2.42 mmol/l
Thyroid stimulating hormone (TSH)	<0.03 $\mu\text{U/ml}$ (Reference range 0.3 - 4.0 $\mu\text{U/ml}$)
Free T4	3.14 ng/dL (Reference range 0.7 - 1.4ng/dL)
Free T3	1.44ng/dL (Reference range 0.2 - 0.5ng/dL)

What is the next most appropriate management step?

	Computer Tomography scan (CT) of the head
	Hydrocortisone
	Fludrocortisone
	Carbimazole
	Intravenous potassium chloride

Dashboard

□ Question 94 of 191

A 24 year old female patient attends the young persons diabetes clinic for a routine follow up. She developed type 1 diabetes mellitus 4 years ago, presenting in DKA at that time. Since then she has been well controlled on carbohydrate counting and basal bolus insulin. Since starting treatment with insulin she has developed vitiligo on her hands and feet which causes her some distress. She is very aware of her skin pigmentation due to her vitiligo and reports on this encounter that she feels her skin in her armpits has gotten darker. She also reports vague symptoms of nausea, weight loss and muscle weakness. She has had to stop playing badminton with her friends due to occasional light-headedness and having fainted once. Her blood sugar diary shows an early morning (fasting) level of 7.1. The highest sugar level recorded is 13.2 with the occasional dip below 4.0.

Examination reveals hyperpigmentation of the axilla bilaterally. There is vitiligo present in both hands and feet but this is consistent with previous examinations. Abdominal examination reveals generalised tenderness with no guarding, some abdominal striae are seen.

Some simple investigations are carried out

Blood Pressure

Lying - 110/76mmHg

Standing 1 minute 94/70mmHg

Standing 3 minutes 86/66mmHg

Hb	12.0 g/dl
Platelets	321 * 10 ⁹ /l
WBC	5.3 * 10 ⁹ /l

Na ⁺	128 mmol/l
K ⁺	5.6 mmol/l
Urea	5.6 mmol/l
Creatinine	82 µmol/l

Bicarbonate	16mmol/l
Random glucose	4.1 mmol/l
HBA1c	58mmol/mol (7.5%)

Given the most likely diagnosis, what is the most important immediate management?

	IV Hypertonic (3%) saline
	IV 0.45% Saline + 5% Dextrose
	Oral Glucose drink
	IV Bicarbonate (1.24%) Infusion
	100mg IV hydrocortisone

Question 97 of 191

A 53 year old obese HGV driver, normally taking BD novomix 30 insulin presents to your outpatient clinic to clarify some driving regulations he had overheard while eating with colleagues. He is extremely tearful and anxious. He is worried about losing his livelihood as a result of his diabetes.

He was first diagnosed with type 2 diabetes 9 years ago and became insulin dependent 2 years ago. He reports good compliance with insulin every day. However, 18 months ago, he took the same units of insulin after exercising and felt giddy. A spot blood glucose check demonstrated 2.8 mmol/l, which improved immediately after drinking lucozade that he carried with him. No hospitalisation was required. He has no other past medical history. He has no visual field or peripheral nerve impairments. What is the advice you give him regarding driving?

<input type="radio"/>	Can continue driving, review in 1 year
<input type="radio"/>	Can continue driving, no further reviews required
<input type="radio"/>	Must stop driving and give up license permanently.
<input type="radio"/>	Must stop driving temporarily and review in 6 months
<input type="radio"/>	Patient can drive type 1 vehicles (cars, motorcycles) but not type 2 vehicles (lorries, HGV) and should reconsider his profession

A 16 year old male presents with 3 months of chronic headache and visual blurring. He has no past medical history and no known family history. On examination, his heart sounds are normal with no added sounds, respiratory examination is unremarkable. He has no focal neurological signs. Fundoscopy reveals papilloedema, hard exudates and flame haemorrhage. His blood pressure is 226/160mmHg. His blood tests and arterial blood gas are as follows:

Na ⁺	145 mmol/l
K ⁺	2.9 mmol/l
Urea	5.4 mmol/l
Creatinine	72 µmol/l

pH	7.49
PaO ₂	13kPa
PaCO ₂	3.4 kPa
Bicarbonate	34 mmol/L

Serum ambulatory renin activity	0.2 pmol/L @ 3-4 hours (normal range 0.8-3.5 pmol/ml/hr)
Serum ambulatory aldosterone	24 pmol/L@ 3-4 hours (normal range 100-800)

What is the optimal long-term treatment?

	Amlodipine
	Ramipril
	Atenolol
	Doxazosin

Question 101 of 191

A 38-year-old man is referred to the pharmacology clinic for review. He is currently managed for hypertension with three anti-hypertensive agents, (ramipril, amlodipine and indapamide). His GP is concerned as he has still not achieved blood pressure target. On examination his blood pressure is 155/95 mmHg, pulse is 78 beats per minute and regular. There are no heart murmurs or bruits. Abdomen is soft and non tender with no masses and his body mass index is 24 kg/m².

Investigations:

Na ⁺	142 mmol/l
K ⁺	3.1 mmol/l
HCO ₃ ⁻	30 mmol/l
Urea	7.0 mmol/l
Creatinine	90 µmol/l

Which of the following is the most likely diagnosis?

<input type="checkbox"/>	Bartter's syndrome
<input type="checkbox"/>	Conn's syndrome
<input type="checkbox"/>	Cushing's syndrome
<input type="checkbox"/>	Licorice overdose
<input type="checkbox"/>	Renal artery stenosis

□ Question 102 of 191

A 24 year old male presented with diabetic ketoacidosis, 12 years after initially diagnosed with type 1 diabetes. He was admitted with the following arterial blood gas:

pH 7.14
Bicarbonate 4 mmol/l

Blood glucose 26 mmol/L
Ketones 9 mmol/L

He was started on an intravenous fixed rate insulin infusion and intravenous fluid rehydration regime in a high dependency setting. At day 3 after the onset of treatment, nursing ask you review the latest blood gas from his arterial line. His fixed rate insulin continues to run. Which of the following blood gases would confirm resolution of his diabetic ketoacidosis?

	pH 7.32, bicarbonate 13, blood glucose 7, ketones 0.3 mmol/L
	pH 7.29, bicarbonate 9, blood glucose 15, ketones 0.9 mmol/L
	pH 7.34, bicarbonate 14, blood glucose 12, ketones 0.9 mmol/L

□ Question 104 of 191

A 28 year old pregnant lady presents to the Emergency Department with palpitations and sweating. She mentions that she has had these symptoms on and off for the past 4 months but that they have worsened over the past few weeks. Now she is feeling worried and wanted to be assessed medically due to her concern she was having a miscarriage. She looks particularly anxious to be in hospital. This is her first pregnancy. She is 7 weeks pregnant. She has had no vaginal bleeding or discharge during the course of her pregnancy. She is normally fit and well.

Initial observations reveal a blood pressure of 130/85 mmHg, a heart rate of 110 beats per minute, a respiratory rate of 19/min, oxygen saturations of 99% on air and a temperature of 37.5 degrees. Examination findings reveal a resting tachycardia and a subtle goitre is noted.

Blood test results are as follows:

Hb	110 g/l
Wcc	12 x10 ⁹ /l
Plt	245 x10 ⁹ /l
CRP	12 mg/l
Na ⁺	140 mmol/l
K ⁺	5.0 mmol/l
Ur	5.7 mmol/l
Cr	110 µmol/l
D-dimer	490 ng/ml
T4	21 mU/l
TSH	<0.05 pmol/l

Given the most likely diagnosis, how should this lady be managed?

--	--

	Watch and wait/symptomatic control with beta blockade
	Radioactive iodine therapy
	Subtotal thyroidectomy
	Propylthiouracil
	Block and replace carbimazole + thyroxine

□ Question 106 of 191

A 56-year-old patient presents to hospital with confusion. He is a long-term smoker. He has a past-medical history of chronic obstructive pulmonary disease, hypertension, bipolar disease and long-term muscular back pain.

On examination he is confused with a Glasgow Coma Scale score of 14 out of 15. He has a pulse rate of 97 beats per minute with a blood pressure of 145/97 mmHg. Respiratory rate is 14 per minute with oxygen saturations of 95% on room air. He has bilateral vesicular breath sounds on auscultation with normal percussion. His abdomen is soft and non-tender with no masses. He has no focal neurology.

Investigations

Hb	102 g/dL
WCC	$8.2 \times 10^9/l$
Platelets	$133 \times 10^9/l$

Na+	146 mmol/L
K+	5.4 mmol/L
Cr	132 μ mol/L
Ur	10.1 mmol/L

Albumin	26 g/L
Adjusted Calcium	3.78 mmol/L
Alkaline Phosphatase	76 IU/L
PTH	Undetectable
Serum ACE	45U/L (10-50)
Serum Electrophoresis	IgG 18 g/L (5-13 g/L) - Polyclonal

Urinary Electrophoresis	Undetectable
-------------------------	--------------

Chest X-ray	Right parahilar opacification 3x4cm
Lumbar Spine X-ray	Normal

What is the likely underlying diagnosis?

<input type="checkbox"/>	Squamous Cell Carcinoma
<input type="checkbox"/>	Multiple Myeloma
<input type="checkbox"/>	Sarcoidosis
<input type="checkbox"/>	Drug induced hypercalcaemia

Question 109 of 191

□ □

A 19 year old gentleman with a background history of asthma presents to the Emergency Department complaining of leg weakness and the inability to walk. He had run a marathon the day before. On examination there is 3/5 weakness of the leg extensors bilaterally. Tone, reflexes and coordination are unimpaired and plantars are downgoing bilaterally. Straight leg raise and sensation to light touch and pain stimulus are unimpaired.

Blood tests show the following:

Hb	13.4g/dl
WBC	$6.2 \times 10^9/l$
Na ⁺	136mmol/l
K ⁺	2.9mmol/l
Urea	6.8mmol/l
Creatinine	104μmol/l

What is the most appropriate treatment in this case?

	Oral potassium and encourage bed rest
	Hourly forced vital capacity measurements and plasma exchange
	Oral potassium and encourage gentle exercise
	Hourly forced vital capacity measurements and IV immunoglobulin
	Plasma exchange and oral potassium supplementation

Question 110 of 191

A 24-year-old lady presents to hospital with increasing confusion. Her parents describe a gradual history of weight loss, lethargy with abdominal cramping. She has no past medical history and is prescribed no regular medications. She lives with her parents. Her mother suffers from hypothyroidism and her father from hypertension which is controlled with bendroflumethiazide.

On examination she is thin, with cool skin and sunken eyes. Her capillary refill time is 3 seconds with dry mucous membranes. Auscultation of her chest reveals bilateral symmetrical vesicular breath sounds. Her abdomen is soft with normal bowel sounds. She is confused with a Glasgow Coma Scale of 14. She has no focal neurology.

Her investigations reveal;

Hb	10.4 g/dL
MCV	90 fL
WCC	$6.4 \times 10^9/l$
Platelets	$170 \times 10^9/l$

Na+	105 mmol/L
K+	5.8 mmol/L
Ur	8.8 mmol/L
Cr	90 μ mol/L
Glucose	3.9 mmol/L

Urinary Osmolality	108 mmol/L
Urinary Sodium	67 mmol/L

Chest X ray	Clear
CT Head	No intracranial abnormalities

What is the most likely diagnosis?

	Adrenal insufficiency
	Laxative abuse
	Hypothyroidism
	Diuretic use
	SIADH

□ Question 2 of 79

A 40 year old man presents to the Emergency Department with tiredness and dizziness (worse on standing) which has been ongoing for the past few months. He had a past medical history of epilepsy and mentions that he has had 'brain surgery' in the past. He is on some medications but cannot remember the names. He has no allergies.

On assessment, he has no focal neurological deficit and cardiovascular/respiratory examination is normal. Observations show a blood pressure of 135/90 mmHg (dropping to 105/82 mmHg on standing), a heart rate of 67 beats per minute, a temperature of 36.2 degrees, oxygen saturations of 94% on air and a respiratory rate of 18/min. Given his medical history, you opt to keep this gentleman in the short stay unit for observation overnight.

Baseline blood tests are as follows:

Hb	125 g/l
WCC	9.2 x10 ⁹ /l
Plt	290 x10 ⁹ /l
CRP	10 mg/l
Gluc	3.9 mmol/l
Na+	138 mmol/l
K+	5.8 mmol/l
Ur	7.2 mmol/l
Cr	100 µmol/l
TSH	0.4 mU/l
T4	5.0 pmol/l

Given the above, what is the most likely underlying diagnosis?

Hypopituitarism

	Hypothyroidism
	Acromegaly
	Pheochromocytoma
	Medication side effects

□ Question 2 of 79

A 40 year old man presents to the Emergency Department with tiredness and dizziness (worse on standing) which has been ongoing for the past few months. He had a past medical history of epilepsy and mentions that he has had 'brain surgery' in the past. He is on some medications but cannot remember the names. He has no allergies.

On assessment, he has no focal neurological deficit and cardiovascular/respiratory examination is normal. Observations show a blood pressure of 135/90 mmHg (dropping to 105/82 mmHg on standing), a heart rate of 67 beats per minute, a temperature of 36.2 degrees, oxygen saturations of 94% on air and a respiratory rate of 18/min. Given his medical history, you opt to keep this gentleman in the short stay unit for observation overnight.

Baseline blood tests are as follows:

Hb	125 g/l
WCC	9.2 x10 ⁹ /l
Plt	290 x10 ⁹ /l
CRP	10 mg/l
Gluc	3.9 mmol/l
Na+	138 mmol/l
K+	5.8 mmol/l
Ur	7.2 mmol/l
Cr	100 µmol/l
TSH	0.4 mU/l
T4	5.0 pmol/l

Given the above, what is the most likely underlying diagnosis?

Hypopituitarism

	Hypothyroidism
	Acromegaly
	Pheochromocytoma
	Medication side effects

□ Question 3 of 79

A 34-year-old woman with a body mass index of 28kg/m² and a background of bipolar disorder presents with excessive thirst, polyuria, and nocturia. Her current medications include lithium and occasional over the counter paracetamol. Her investigation results are as shown below.

Hb	120 g/l
Platelets	220 * 10 ⁹ /l
WBC	5.2 * 10 ⁹ /l

Na ⁺	128 mmol/l
Ca ⁺	2.32 mmol/l
Urea	3 mmol/l

Fasting plasma glucose 7.2 mmol/L

Water deprivation test:

Initial plasma osmolality low

Urine osmolality 300-400 mOsm/kg

Urine osmolality post desmopressin 400 mOsm/kg

Final plasma ADH moderate

What is the most likely cause of her symptoms?

	Type 2 diabetes mellitus
	Nephrogenic diabetes insipidus
	Type 1 diabetes mellitus
	Primary polydipsia

Dashboard

Overall score: **0%**

□ Question 4 of 79

You are the endocrinology registrar in the diabetic clinic. You see a 45 year old female with type 2 diabetes mellitus. She is generally well in herself. She currently takes metformin 500 mg bd and has no other regular medications. She has good hypoglycaemia awareness and rarely gets hypoglycaemic episodes. Blood sugars on home monitoring range between 5 and 9.

Routine blood tests show:

Hb	131 g/l
Plt	$131 \times 10^9/l$
WCC	$13.1 \times 10^9/l$
Na+	131 mmol/l
K+	3.1 mmol/l
Urea	3.1 mmol/l
Creatinine	31 $\mu\text{mol/l}$
eGFR	79 ml/kg/1.73m ²
HbA1c	46 mmol/mol (6.4%)

Urinalysis: PRO+, GLUC +, nil else.

Urinary ACR (albumin:creatinine ratio) is 3.6 mg/mmol.

On examination, her BMI is 21 kg/m², she has good peripheral sensation, fundi look normal. Chest is clear to auscultation, heart sounds are normal with no murmurs and her abdomen is soft and non tender.

Her heart rate is 72 beats per minute and regular, blood pressure is 124/75 mmHg, respiratory rate is 20/min, oxygen saturations are 98% on air and temperature 36.8 degrees.

What medication should be commenced in this lady for her ongoing management?

	Commence gliclazide 80mg BD
	Commence ramipril 1.25mg OD
	Increase metformin to 500 mg TDS
	Commence candesartan 2 mg OD
	Commence antibiotics for suspected UTI

Dashboard

Overall score: **0%**

□ Question 6 of 79

A 62-year-old man presents to hospital with a three day history of tiredness, muscle aches, a fever and pain at the front of his neck. Two weeks ago he had an upper respiratory tract infection which he treated himself with paracetamol and oral decongestants. He did not receive any antibiotics. His only past medical history is mild arthritis of the right knee and he only takes occasional antihistamines during summer time.

On examination, he appears anxious with a fine resting tremor. He has a temperature 38.1°C, a pulse rate of 125 per minute which is regular and normal in character and a blood pressure of 131/78 mmHg. Heart sounds 1 and 2 were present with no added sounds and his chest was clear on auscultation. His abdomen was soft and non-tender with no organomegaly. Neurological examination was unremarkable apart from the resting tremor. Neck examination reveals a diffusely enlarged and tender thyroid gland.

Blood tests are requested and the results are as follows:

Hb	14.0 g/dl	
Platelets	378 * 10 ⁹ /l	
WBC	8.9 * 10 ⁹ /l	
ESR (Westergren)	94 mm/1st hour	Normal range 0-30
Free T4	214 nmol/l	
Free T3	192 nmol/L	
Plasma TSH	<0.05 mU/l	

Which of the following investigations is likely to be most helpful in establishing the diagnosis?

	Blood cultures
	Serum anti-thyroid antibodies
	Ultrasound scan of neck

	Radioactive iodine uptake scan
	Fine needle aspiration

Dashboard

□ Question 7 of 79

A 24-year-old female presents to the emergency department with severe abdominal pain which had developed over for the last few hours. The pain was central, severe and stabbing in nature associated with vomiting. She was in hysterics and was extremely agitated and confused. Past medical history included asthma and depression. Two days earlier she had seen her GP for dysuria and been prescribed trimethoprim.

She was a student studying chemistry at university and had recently been out late several nights drinking excess alcohol to celebrate passing her exams. On examination, she was unwell, extremely clammy, distressed with generalised abdominal tenderness and weakness in both legs with areflexia. Heart sounds and chest were clear. Observations showed a blood pressure 190/100 mmHg, heart rate 126/min, regular and temperature 37.9°C.

Which investigation is most likely to be diagnostic?

	Urinary catecholamines
	Abdominal ultrasound
	Urinary porphobilinogen
	Lumbar puncture
	Blood cultures

Dashboard

Question 9 of 79

A frail 82 year old gentleman was brought in by his daughter, who found him on the floor in his flat. He had tripped in a mechanical and had been unable to get back up, lying on the floor for the past 3 days. On examination, he appears extremely dehydrated but has no specific focal weakness, systemic examination is unremarkable. He has sustained no musculoskeletal injuries. His blood tests are as follows:

Na ⁺	168 mmol/l
K ⁺	6.0 mmol/l
Urea	24 mmol/l
Creatinine	260 µmol/l (baseline 107 three months ago)
Creatinine kinase	11,000 mmol/l

ECG shows normal sinus rhythm at 99/ minute.

You diagnose him with rhabdomyolysis and an acute kidney injury, likely of pre-renal cause. Intravenous fluid rehydration is initiated with intravenous 5% dextrose. You ask your colleague to check the patients blood tests in 12 hours.

What is the aim in correcting the patients hypernatraemia?

	Reduce blood sodium to under 145 mmol/l as quickly as possible
	Reduce blood sodium by 0.5mmol/hr. The drop in 12 hours should be no greater than 6 mmol/l
	Reduce blood sodium by 1mmol/hr. The drop in 12 hours should be no greater than 12 mmol/l
	Aim for blood sodium above 145 mmol/l
	Blood sodium does not require monitoring if intravenous fluids is running, CK falling and renal function improving

Question 9 of 79

□ Question 14 of 79

A 72-year-old Japanese female presents to the emergency department with sudden onset shortness of breath associated with palpitations. She has previously experienced similar palpitations 6 months ago but did not seek medical attention. She was last completely well and described by her daughter to be at baseline 24 hours ago when they had dinner together. The patient denies any chest pain, nausea, vomiting or sweating. On examination, the patient is pyrexial at 38.2 degrees and tachycardic, with a regular pulse at 130-140 beats per minute. Heart sounds demonstrate a gallop rhythm; auscultation of her chest reveals bibasal inspiratory coarse crackles and no wheeze. She has bilateral mild lower limb pitting oedema to low ankles. Examination of the abdominal and neurological systems is unremarkable. A chest radiograph demonstrates bibasal alveolar shadowing with mild bilateral pleural effusions. An ECG demonstrates sinus tachycardia at 130 beats per minute. Blood tests are as follows:

Hb	123 g/l
Platelets	299 * 10 ⁹ /l
WBC	9.5 * 10 ⁹ /l

Na ⁺	139 mmol/l
K ⁺	4.2 mmol/l
Urea	7.2 mmol/l
Creatinine	98 µmol/l

TSH	< 0.01 mU/l
Free T4	140 pmol/l
Free T3	40 pmol/l

Nursing staff have kindly taken blood cultures and taken measures to cool the patient. What is the next most appropriate immediate treatment?

--	--

	Intravenous propranolol
	Lugol's iodine
	Oral carbimazole
	Oral propylthiouracil
	Oral prednisolone

Question 16 of 79

An 18-year-old migrant from Syria presents to you after recent successful application for asylum. He has no family with him in the country. Since he can remember he gets severe burning pain and tingling in the hands and feet, particularly after exertion or when weather temperatures are extremely hot or cold. He remembers once having a transient episode of slurred speech and right facial droop that lasted less than 24 hours. He has never had the opportunity to consult about his problems. Physical examination reveals a rash of blue-black telangiectasia across his trunk and a mid-systolic murmur heard loudest in the apex and radiating into the axilla. The examination is otherwise unremarkable. He recalls that his younger brother, who died some years ago, had similar problems and his sister, who he is no longer in touch with, seems to have not had any problems. Which of the following findings is consistent with the underlying diagnosis?

	Positive anticentromere antibodies
	Deficiency in plasma levels of alpha-galactosidase
	Aortic coarctation visualised by aortic angiography
	Raised HBA1C
	Excessive excretion of mucopolysaccharides in urine

□ Question 18 of 79

A 48-year-old man is referred to the outpatient department by his GP, having experienced tremor, heat intolerance and 2 kg weight loss over the last 6 weeks. His past medical history includes having atrial fibrillation for which he takes warfarin and amiodarone. He is a non-smoker and drinks on average 10 units of alcohol per week.

Blood tests are performed and reveal:

Hb	142 g/l	
Platelets	$220 \times 10^9/l$	
WBC	$7.2 \times 10^9/l$	
Na ⁺	140 mmol/l	
K ⁺	4.2 mmol/l	
Urea	4.5 mmol/l	
Creatinine	45 μ mol/l	
Thyroid stimulating hormone (TSH)	0.03 mu/l	
Free thyroxine (T4)	29 pmol/l	
Total T3 (TT3)	252 ng/dL	Normal range 75 -200 ng/dL

A colour flow Doppler sonography of the thyroid is performed and shows absent vascularity and gland destruction.

What is the most likely diagnosis?

	Type 1 amiodarone-induced thyrotoxicosis
	Type 2 amiodarone-induced thyrotoxicosis
	Grave's disease

	Hashimotos thyroiditis
	De Quervains thyroiditis

□ Question 19 of 79

A 27-year-old female was seen in the general medicine outpatient clinic following a referral by her GP. She had presented to her GP feeling generally tired for the last few months. Her GP organised a blood screen revealing no abnormalities except the presence of a potassium level of 2.8 mmol/l. Her GP subsequently repeated the test four weeks later revealing a level of 2.6 mmol/l, leading to the referral to the clinic. Other than the tiredness she was well in herself, denying all other symptoms. She denied specifically the presence of any cardiovascular and muscular symptoms and had never collapsed. Her past medical history was unremarkable and she was taking no prescribed medication. There was no family history of note.

Examination revealed a well 27-year-old lady. Her blood pressure was 108/78 mmHg, heart rate 82 bpm and BMI 23kg/m². Examination of her cardiovascular and respiratory systems revealed the presence of normal heart sounds, a JVP of 3cm and warm well perfused peripheries. Examination of her gastrointestinal and neurological systems was unremarkable.

Investigations conducted at the clinic revealed the following results:

Hb	122 g/l
Platelets	242 * 10 ⁹ /l
WBC	7.8 * 10 ⁹ /l

Na ⁺	132 mmol/l
K ⁺	2.5 mmol/l
Urea	7.2 mmol/l
Creatinine	68 µmol/l
Bicarbonate	37 mmol/l

Serum renin	824 (NR 100-500 pmol/l)
Serum aldosterone	82 (NR 55-250 pmol/l)

TSH	1.2 mu/l
-----	----------

24 hour urine result:

Na+	28 (NR <20mmol/L if hyponatraemia)
K+	45 (NR <10mmol/l if hypokalaemic)
Calcium	0.8 (NR <7.5 mmol/24hrs)

What is the most likely diagnosis?

<input type="radio"/>	Addison's disease
<input type="radio"/>	Gitelman's syndrome
<input type="radio"/>	Conn's disease
<input type="radio"/>	Bartter's syndrome
<input type="radio"/>	Laxative abuse

□ Question 21 of 79

A 15-year-old girl was seen in clinic with lethargy, weakness worsening over the past 4 weeks. She also complains of recurrent muscle cramps in her legs, causing her to have trouble sleeping. On further questioning she admits to urinary frequency, passing urine up to ten times a day, and feels dehydrated all the time. She has also previously been diagnosed with cyclical vomiting syndrome and vomits 2-3 times a week.

On examination, she is thin, with a body mass index of 17.5kg/m². Her heart rate is 89 bpm and blood pressure is 103/76 mmHg.

The results of the investigations at the clinic are as follow:

C Reactive protein	3 mg/l
Haemoglobin	158 g/l
White cell count	$7.6 \times 10^9/L$
Na+	136 mmol/l
K+	2.9 mmol/l
Urea	7.2 mmol/l
Creatinine	108 μ mol/l
Corrected calcium	2.42 mmol/l
Serum renin levels	8.6 ng/ml/hr
Serum aldosterone levels	750 ng/l

Urine chloride levels	90 mmol/l
Urine sodium concentration	88 mmol/l
Urine potassium levels	49 mmol/l
Urine calcium:creatinine ratio	0.3 (high)

Venous blood gas result

pH	7.532
Bicarbonate	37 mmol/l

Which of the following diagnosis would be consistent with the above clinical picture?

	Liddle's syndrome
	Conn's syndrome
	Familial idiopathic hypercalciuria
	Bartter's syndrome
	Gitelman's syndrome

□ Question 23 of 79

A 23 year old woman with known type 1 diabetes mellitus is brought to the emergency department resus area unwell. On taking her history she mentions that she has had a cough for the past three days with fevers, and today she developed vague abdominal pain. A blood gas take on admission shows:

pH	7.21
pO ₂	14.8 kPa
pCO ₂	3.1 kPa
Bicarbonate	14 mEq/L
Base excess	-10.5 mmol/L
Na ⁺	145 mmol/L
K ⁺	5.3 mmol/L
Glucose	40.1 mmol/L
Lactate	2.3 mmol/L

Urinalysis:

Leucocytes	-
Blood	-
Glucose	+++
Ketones	++++

The patient has been given 500mls of 0.9% saline as a stat bag, followed by a further 1L of 0.9% saline over 60 minutes, and her observations are as follows:

Respiratory rate	25 breaths/minute
Saturations	99% on 2L

Temperature	37.7°C
Blood pressure	106/67 mmHg
Heart Rate	102 beats/minute

The nurses weigh her at 60 Kg

Her lab results are pending

Which fluid and insulin regimen would be the most appropriate at her current stage?

	1L of 0.9% Normal Saline with 20mmol of KCl added given over 2 hours + IV insulin at 6 units per hour.
	1L of 0.9% Normal Saline with 40mmol of KCl added given over 2 hours + IV insulin at 6 units per hour.
	1L of 0.9% Normal Saline with 20mmol of KCl added given over 2 hours + Sliding scale IV insulin based on capillary blood sugar readings
	1L of 0.9% Normal Saline with 20mmol of KCl added given over 2 hours + 1L of 1.26% sodium bicarbonate solution over 8h + IV insulin at 6 units per hour.
	1L of 0.9% Normal Saline with 40mmol of KCl added given over 4 hours + IV insulin at 6 units per hour.

□ Question 25 of 79

A 72 year old female presents with 5 days of generally decline and a recent productive urinary tract infection, treated with oral antibiotics in the community by the GP. She is known to be a type two diabetic, diagnosed 28 years ago and insulin dependent for the past 6 years. She is normally on 46 units lantus, 23 units TDS novorapid. On examination, she is not orientated in time or place, GCS 14/15. She has no focal neurology, chest and cardiovascular auscultation are unremarkable. You demonstrate suprapubic tenderness on deep palpation but abdomen is other soft and nontender, bowel sounds are present. She appears extremely dehydration: her mucous membranes are dry, peripheries cool with capillary refill time of 4 seconds and JVP +1 cm above the angle of Louis. Her blood sugar is 31mmol/L and a venous blood gas demonstrates pH 7.22, lactate 2 mmol/l, ketones 5 mmol/l. A urine dip is awaited. What is the most likely diagnosis?

	Hyperglycaemic hyperketotic state
	Hyperglycaemia secondary to poor medical compliance during recent acute illness
	Urosepsis secondary to inadequately treated UTI
	Diabetic ketoacidosis
	Dehydration secondary to poor oral intake

Dashboard

□ Question 26 of 79

A 68-year-old Indian patient presents to the emergency department with facial tetany, muscle cramps and paraesthesia of her fingers and toes. This is her second admission with similar symptoms. Her past medical history includes diffuse cutaneous systemic sclerosis with gastrointestinal, cutaneous and pulmonary manifestations. She was also diagnosed with vitamin D deficiency two years ago and receives regular vitamin D supplements. Her blood tests are as follows:

Hb	124 g/l
WBC	$8.0 \times 10^9/l$
Na ⁺	141 mmol/l
K ⁺	4.3 mmol/l
Urea	6.5 mmol/l
Creatinine	90 μ mol/l
CRP	15 mg/l
Corrected calcium	1.68 mmol/l
Phosphate	1.4 mmol/l
Magnesium	0.28 mmol/l
PTH	2 pmol/L (normal range = 8.5-12)
Amylase	14 u/l

Her symptoms improve with intravenous calcium replacement and intravenous magnesium replacement, correcting both electrolytes to within normal range. What is the underlying cause for these metabolic disturbances in this patient?

	Hypomagnesaemia
	Primary hypoparathyroidism
	Insufficient vitamin D supplementation

	Chronic kidney failure
	Chronic pancreatitis

□ Question 27 of 79

A 38-year-old woman is referred by her GP for management of Graves' disease, diagnosed by the presence of a goitre, suppressed thyroid stimulating hormone, and presence of thyroid antibodies on screening. She has no past medical history of note, drinks 10 units of alcohol per week and smokes 20 cigarettes per day. On examination her blood pressure is 112/88 mmHg, pulse is 89 beats per minute and regular, she has a fine tremor. There is a smooth goitre and marked proptosis.

Which of the following has the greatest negative impact on prognosis of her thyroid eye disease?

	Alcohol consumption
	Cigarette smoking
	DR4 HLA type
	LATS titre
	Use of block replace therapy

□ Question 28 of 79

A 24 year old student nurse is brought to the Emergency Department having collapsed at work. Apart from depression for which she takes sertraline, she has no other past medical history. This is her third collapse in a month. On each attendance capillary blood glucose measurements have been < 4mmol/L. An oral glucose tolerance test performed two weeks previously by her GP was normal.

Today:

C-peptide	3.9ng/ml (0.8 - 3.1ng/ml)
Glucose	3.4mmol/L

What is the most appropriate next investigation?

	Early morning C-peptide levels
	Toxicology screen
	CT scan of pancreas
	No further investigations, advise her to stop self-administering insulin
	72 hour fast

□ Question 30 of 79

A 60-year-old man presented with history of excessive urination especially during night which disturbs his sleep, excessive thirst and tiredness for the past 2 months. He was a known HIV positive patient for which he was on highly active anti-retroviral therapy (HAART) since 6 months. Clinical examination was within normal limits. HIV related diabetes mellitus was suspected by the treating physician. His blood investigations are as follows-

Hb	150 g/l
Platelets	$150 \times 10^9/l$
WBC	$7 \times 10^9/l$
Fasting blood glucose	10 mmol/l
Post prandial blood glucose	13.9 mmol/l
Serum creatinine	130 $\mu\text{mol/L}$

He was planned to be started on metformin therapy. Which of the following investigations is important to be checked before starting metformin in this patient?.

	Liver enzymes
	Venous lactate
	Serum triglycerides
	Serum albumin
	Serum ammonia

Question 30 of 79

HIV related diabetes mellitus was suspected by the treating physician. His blood investigations are as follows-

Hb	150 g/l
Platelets	150 * 10 ⁹ /l
WBC	7 * 10 ⁹ /l
Fasting blood glucose	10 mmol/l
Post prandial blood glucose	13.9 mmol/l
Serum creatinine	130 umol/L

He was planned to be started on metformin therapy. Which of the following investigations is important to be checked before starting metformin in this patient?.

	Liver enzymes
	Venous lactate
	Serum triglycerides
	Serum albumin
	Serum ammonia

□ Question 31 of 79

A 19-year-old man is brought by ambulance to the emergency department. The patient himself was too unwell to provide a coherent history but his mother reports that he had been very unwell with loss of appetite and abdominal pain for the past two days. She had also noted a significant weight loss in her son over the past six months and that he had been unusually fatigued over the same time period. The patient had no previous family history although his older sister had recently been diagnosed with pernicious anaemia.

Examination showed the patient to be tachypnoeic and tachycardic with a central capillary refill time of six seconds. Respiratory and cardiovascular examination was otherwise unremarkable. Abdominal examination revealed some inconsistent tenderness without obvious signs of localised peritonism.

Please see below for results of initial investigations.

Urea	10.6 mmol / L
Creatinine	134 micromol / L
Sodium	149 mmol / L
Potassium	5.8 mmol / L
Fingerpick blood glucose	42 mmol / L
Fingerpick blood ketones	7.5 mmol / L

Venous blood gas (room air)

pH	7.09
PCO ₂	16 mmHg (reference 32-43)
PO ₂	52 mmHg (reference 70-100)
Bicarbonate	10.9 mmol / L (reference 20.0-26.0)
Chloride	107 mmol / L (reference 99-108)
Lactate	4.9 mmol / L

Portable chest x-ray: poor quality film secondary overlying artefact; no free air under diaphragm, lung fields clear, no pneumothorax.

Electrocardiogram: sinus tachycardia at 129; normal intervals and axis; QRS morphology normal; T wave morphology normal.

What is the correct immediate management for this patient?

	1000 mg calcium gluconate
	10 mL 8.4 % sodium bicarbonate
	1000 mL 0.9 % saline
	1000 ml 0.45 % saline
	Intravenous insulin bolus

□ Question 36 of 79

A 43 year old man has been referred to endocrinology clinic for blood pressure investigation and management. Over the past year the patient has had a persistently raised blood pressure between 170/100mmHg and 180/110mmHg. Despite starting the patient on ramipril 5mg once daily four weeks ago the patient's blood pressure on this visit remained raised at 164/93mmHg.

During the history taking part of the consultation the patient mentions that he has been troubled with headaches for the past year, and has noticed that his stool frequency has increased and his stools have become looser. He tells you that he's rather embarrassed to admit that he's been having flushing episodes, and feels that his clothes are much looser than they were 1 year ago.

On discussing his family history he mentions that both his mother and his father had to have cancerous lumps removed in their middle ages. His mother had a breast lump removed, and his father had some form of pancreatic mass removed.

On examination the patient is tall with a wide arm span. Examination of the cardiovascular system reveals only a minor tachycardia of 95bpm and a quiet systolic flow murmur not radiating to the carotids. Abdominal examination reveals no palpable masses, and examination of his lungs is completely normal.

The GP had previously arranged a 24h urinary catecholamine test; results are as follows:

Total urine catecholamines 210mcg/24hr. This is raised.

As a follow up to this test the GP had arranged a CT of the patient's abdomen and pelvis which is reported as normal apart from a few incidental simple renal cysts.

Urinalysis in clinic today shows:

Leucocytes	-
Blood	-
Glucose	+
Ketones	-

Which test is most likely to elucidate the cause of the patient's hypertension?

	Pentagastrin stimulation test
	24h urinary HIAA
	MRI renal angiography
	GH, IGF-1 and 'gut hormones'
	MIBG (metaiodobenzylguanidine) scan

Dashboard

Overall score: **0%**

Question 37 of 79

You are asked to review a 62 year-old Caucasian man who is an inpatient on the medical admissions unit. He is currently being treated for a left lower lobe community acquired pneumonia. You note consumed alcohol excessively prior to admission but has been abstinent for the last four days.

During this admission it has been noted that serial bloods glucose measurements have been elevated and subsequently a new diagnosis type two diabetes has been made. The admission consultant noted Cushingoid featured and requested an overnight low dose dexamethasone suppression test. The results are as follows:

8am Cortisol after 1mg dexamethasone at 11pm the previous day	438 nmol/L
Reference range for serum cortisol	170-540 nmol/L

What is most appropriate next step in the investigation of this gentleman?

	Serum ACTH measurement
	Midnight serum cortisol
	Inferior petrosal sinus sampling post CRH administration
	High dose dexamethasone suppression test
	MRI pituitary

Dashboard

Overall score: 0%

□ Question 38 of 79

A 22-year-old female, who is known to have type 1 diabetes mellitus, presents with weight loss, anorexia and fatigue for the last six months.

Her diabetes was well controlled with soluble insulin three times daily and long acting insulin in the evening but during the last six months she noticed that her insulin requirement has generally decreased and on three occasions she had hypoglycaemic attacks.

During the same time period she had lost approximately 7 Kg in weight and had generally lost her appetite. She had also been amenorrhoeic over the last three months.

On examination, she is thin (BMI 18), with a pulse rate of 70 beats per minute and a blood pressure of 110/70 mmHg with a postural drop.

Investigations reveal:

Serum sodium	125mmol/L
Serum potassium	5.3mmol/L
Serum urea	7.4mmol/L
Serum creatinine	100 mol/L
Serum glucose	7.5mmol/L
HbA1c	6.0%
Serum free T4	7.5 pmol/L
Serum TSH	5.5 pmol/L
Serum oestradiol	70 pmol/L (130-850)
Serum LH	2.5 mU/L (2-10)
Serum FSH	2.2 mU/L (2-10)
Serum prolactin	400 mU/L (50-450)

Serum calcium	2.9 mmol/l
Serum phosphate	0.8 mmol/l

What is the most appropriate investigation for this patient?

	Thyroid autoantibodies
	PTH concentration
	Short synacthen test
	Pregnancy test

□ Question 38 of 79

A 22-year-old female, who is known to have type 1 diabetes mellitus, presents with weight loss, anorexia and fatigue for the last six months.

Her diabetes was well controlled with soluble insulin three times daily and long acting insulin in the evening but during the last six months she noticed that her insulin requirement has generally decreased and on three occasions she had hypoglycaemic attacks.

During the same time period she had lost approximately 7 Kg in weight and had generally lost her appetite. She had also been amenorrhoeic over the last three months.

On examination, she is thin (BMI 18), with a pulse rate of 70 beats per minute and a blood pressure of 110/70 mmHg with a postural drop.

Investigations reveal:

Serum sodium	125mmol/L
Serum potassium	5.3mmol/L
Serum urea	7.4mmol/L
Serum creatinine	100 mol/L
Serum glucose	7.5mmol/L
HbA1c	6.0%
Serum free T4	7.5 pmol/L
Serum TSH	5.5 pmol/L
Serum oestradiol	70 pmol/L (130-850)
Serum LH	2.5 mU/L (2-10)
Serum FSH	2.2 mU/L (2-10)
Serum prolactin	400 mU/L (50-450)

Serum calcium	2.9 mmol/l
Serum phosphate	0.8 mmol/l

What is the most appropriate investigation for this patient?

	Thyroid autoantibodies
	PTH concentration
	Short synacthen test
	Pregnancy test
	Random cortisol concentration

□ Question 39 of 79

A 52-year-old lady was seen in the general medicine clinic with aches and pains. The pains were present in her arms and legs, and not associated with her joints. They have been present for several months, and she was unable to identify any precipitating factors. She also felt that on occasion she felt generally weak and tired, though denied the presence of any specific weakness. Her past medical history comprised of epilepsy which was well controlled with phenytoin 500mg BD for several years, as well as hypertension and asthma. In addition to phenytoin 500mg BD she was prescribed ramipril 5mg OD, Clenil modulite 200mcg BD, salmeterol 100mcg BD and Elleste duo for the last six months. Upon specific questioning, she stated that she ate a nutritionally balanced diet, and that she had not suffered a previous fracture. Her mother was diagnosed with osteoporosis when she was 64-years-old, and she did not smoke. She drank 10 units of alcohol per week.

On examination, she was systemically well, with a blood pressure of 132/68 mmHg, heart rate 84, respiratory rate 16/min and body mass index of 23. Examination of her cardiovascular system revealed the presence of normal heart sounds and was unremarkable. Examination of the respiratory and gastrointestinal systems was likewise unremarkable except for the presence of gingival hypertrophy. Examination of the musculoskeletal system revealed the presence of Heberden's nodes but was also otherwise unremarkable with a full range of movement in all joints. Examination of the neurological system was normal with a power of 5/5 in all muscle groups and normal sensation, tone and coordination. Cranial nerve and fundoscopy examinations were unremarkable. Examination of the thyroid gland was unremarkable.

Investigations revealed the following results:

Bilirubin	22 μ mol/l
ALP	262 u/l
ALT	23 u/l
Albumin	42 g/l
Protein	76 g/l
Globulin	34 g/l
Adjusted calcium	2.06 mmol/l
Phosphate	0.78 mmol/l
Vitamin D level	pending result

Parathyroid hormone	88 (NR 11-54 pg/ml)
IgG	11.2 g/L (NR 7.0 18.0)
IgA	3.2 g/L(NR 0.8 4.0)
IgM	2.1 g/L (NR 0.4 2.5)

Urinary Bence Jones Protein: negative

What is the most likely underlying diagnosis?

<input type="radio"/>	Fibromyalgia
<input type="radio"/>	Paget's disease
<input type="radio"/>	Primary hyperparathyroidism
<input type="radio"/>	Osteoporosis
<input type="radio"/>	Osteomalacia

□ □

A 38-year-old woman is referred to the outpatient department by her GP with pain in her calves when walking 50 meters. She reports no other symptoms and has no other past medical history other than migraine. She is on no regular medication and her family history includes her mother having diabetes and her father dying of a heart attack aged 46. She currently smokes 35 cigarettes per day and drinks a glass of wine every evening. Her occupation is as a financial advisor.

Examination reveals tendon xanthomas affecting the extensor tendons of his fingers. On examining her face it is noticed she has xanthelasma around both eyes and corneal arcs.

Which of the follow is the most likely diagnosis?

	Tangier disease
	Homozygous familial hypercholesterolaemia
	Heterozygous familial hypercholesterolaemia
	Familial hypertriglyceridaemia
	Apo CII deficiency

□ Question 43 of 79

A 50-year-old gentleman presents to review in the endocrine clinic. He was normally taking metformin and gliclazide, but over the last six months has also been prescribed a GLP-1 mimetic. He was started on a GLP-1 mimetic because of poor diabetic control and concerns about starting insulin. He does not want to start insulin because he is a truck driver and worried about losing his driving license. He had previously tried the combination of metformin, gliclazide and pioglitazone, but this had also failed to control his HbA1c.

Over the last six months his HbA1c has reduced from 81mmol/ mol to 80mmol/ mol, and he has lost two kg in weight. What is the most appropriate action?

	Continue current treatment and review in one year
	Continue current treatment and review in six months
	Change to metformin, gliclazide and pioglitazone
	Offer to add on insulin
	Stop GLP-1 mimetic and offer insulin treatment

Primary prevention

(10-year cardiovascular risk $\geq 10\%$ OR
most type 1 diabetics OR
CKD if eGFR $< 60\text{ml/min/m}^2$)

Atorvastatin 20mg od

(if non-HDL has not fallen by $\geq 40\%$ then
consider titrating up to 80mg)

Question 44 of 79

A 19 year-old man is referred by his GP to the outpatient department after having several episodes of collapse at college. He reports that during these episodes he feels tired and 'blacks out'. Afterwards, he feels shaky and weak. There is no tongue biting or incontinence during these episodes and the patient reports that he often feels dizzy after standing up too quickly from a chair. The only other symptoms he reports is a sore throat that has persisted for a few weeks and lethargy.

On examination of the patient's mouth and throat, there are some white plaques located at the back of the tongue and throat. His sitting blood pressure is 130/80 mmHg and his standing blood pressure is 95/70 mmHg. He is otherwise well.

Blood tests are performed and reveal:

Hb	13.9 g/dL
Platelets	$200 \times 10^9/l$
WBC	$6.2 \times 10^9/l$
Na ⁺	132 mmol/l
K ⁺	5.1 mmol/l
Urea	4.7 mmol/l
Creatinine	81 μ mol/l
Calcium	1.9 mmol/l
Random glucose	3.9 mmol/l

What is the most likely diagnosis?

<input type="checkbox"/>	Type II polyglandular autoimmune syndrome
<input type="checkbox"/>	Thymoma
<input type="checkbox"/>	Type 1 polyglandular autoimmune syndrome

	Type III polyglandular autoimmune syndrome

□ Question 45 of 79

A 70-year-old woman with a history of type 2 diabetes mellitus and hypertension is reviewed in clinic. You can see from the records there is no evidence of diabetic retinopathy, chronic kidney disease or cardiovascular disease.

Her current medication is as follows:

- simvastatin 40mg on
- ramipril 10mg od
- amlodipine 5mg od
- metformin 1g bd

Recent blood results are shown below:

Na ⁺	142 mmol/l
K ⁺	4.4 mmol/l
Urea	7.2 mmol/l
Creatinine	86 µmol/l
HbA1c	45 mmol/mol (6.3%)

Urine dipstick shows no proteinuria. Her blood pressure today in clinic is 134/76 mmHg.

What is the most appropriate course of action?

	Add gliclazide
	Increase amlodipine
	Increase ramipril
	Add losartan

No changes to medication required

□ Question 49 of 79

A 58 year-old man presents with a two month history of weight loss and a one week history of increasing confusion. His partner reports that his clothes are now loose on him and that he has started to forget things and that he has been unable to reach for objects off the top shelf at the supermarket over the last two months due to increasing weakness. Six weeks ago he had been treated for an islet cell carcinoma of the pancreas with chemotherapy and has no other past medical history.

Examination reveals an abbreviated mental test score of 5/10 and weakness in the shoulders and getting out of the chair. Heart sounds 1 and 2 are present with no added sounds, his chest is clear and the abdomen is soft and non-tender.

Observations reveal a blood pressure of 158/95 mmHg, a pulse rate of 90 beats per minute, a temperature of 37.5°C and a respiratory rate of 14 breaths per minute. Random blood glucose is 16.2 mmol/L.

Blood tests are performed and reveal:

Hb	14.2 g/l
Platelets	180 * 10 ⁹ /l
WBC	4.9 * 10 ⁹ /l
Na ⁺	150 mmol/l
K ⁺	2.6 mmol/l
Urea	5.2 mmol/l
Creatinine	100 µmol/l
Bilirubin	15 µmol/l
ALP	70 u/l
ALT	28 u/l
γGT	47 u/l
Albumin	48 g/l

What is the most likely diagnosis?

	Paraneoplastic encephalitis
	Cerebral metastases
	Post chemotherapy Cushing's syndrome
	Post chemotherapy hypothyroidism
	Ectopic ACTH secretion

□ Question 49 of 79

A 58 year-old man presents with a two month history of weight loss and a one week history of increasing confusion. His partner reports that his clothes are now loose on him and that he has started to forget things and that he has been unable to reach for objects off the top shelf at the supermarket over the last two months due to increasing weakness. Six weeks ago he had been treated for an islet cell carcinoma of the pancreas with chemotherapy and has no other past medical history.

Examination reveals an abbreviated mental test score of 5/10 and weakness in the shoulders and getting out of the chair. Heart sounds 1 and 2 are present with no added sounds, his chest is clear and the abdomen is soft and non-tender.

Observations reveal a blood pressure of 158/95 mmHg, a pulse rate of 90 beats per minute, a temperature of 37.5°C and a respiratory rate of 14 breaths per minute. Random blood glucose is 16.2 mmol/L.

Blood tests are performed and reveal:

Hb	14.2 g/l
Platelets	180 * 10 ⁹ /l

□ □

A 20-year-old nurse with no past medical history presents following a collapse with a blood sugar 1.5 mmol/l . You phone her general practitioner and find out she has had 6 month history of episodes hypoglycemia. The cause has not been established and she is awaiting an outpatient endocrinology opinion. In hospital her bloods come back showing an insulin level 350 mIU/L(18-276) 1 hour after lunch. Her C-peptide level at this time is 3.50 ng/ml (0.51 to 2.72). Her TSH is 0.03 mIU/L . What test should be performed next?

	Urgent MRI pancreas
	Urgent ultrasound thyroid
	Urgent MRI head
	Urine or serum sulphonylurea levels
	Short Synacthen test

□ Question 51 of 79

A 26-year-old primigravida lady is brought to the hospital at 17 weeks gestation with worsening confusion. Her husband states that she has been vomiting profusely for the past 3 weeks. She has been unable to eat but she has managed to keep down small amounts of fluid.

Her past medication history is unremarkable and she takes no regular medications.

On examination, she is afebrile. Her pulse is 108bpm and her blood pressure is 103/68mmHg. She is alert but disorientated to time and place. Cranial nerve examination is remarkable for bilateral VIth nerve palsy and multi-directional nystagmus. Peripheral neurological examination reveals MRC grade 4/5 power in both lower limbs. Her lower limb jerks are absent and there is bilateral loss of distal vibration sense. Her plantar responses are downgoing.

A set of blood tests are requested:

Hb	117 g/l	Na ⁺	132 mmol/l
Platelets	362 * 10 ⁹ /l	K ⁺	2.8 mmol/l
WBC	12.3 * 10 ⁹ /l	Urea	8.9 mmol/l
Neuts	10.1 * 10 ⁹ /l	Creatinine	112 µmol/l
Lymphs	1.9 * 10 ⁹ /l	CRP	17 mg/l
Eosin	0.01 * 10 ⁹ /l	Glucose	3.1 mmol/l

What is the most appropriate treatment?

	Folic acid
	Niacin
	Vitamin B12
	Intravenous dextrose

□ Question 52 of 79

A 25-year-old woman is brought to the emergency department by ambulance after being found unwell by friends. Collateral history reported by the paramedics indicated that the patient had been unwell for 3 days with vomiting and diarrhoea. Her housemate said that the patient had been unable to eat since becoming unwell and that he did not think she had been taking her regular insulin during that time. The patient herself was too disorientated to give any history. The paramedics had found both novorapid and lantus insulin pen devices in the patients fridge.

General examination indicated a drowsy and dehydrated patient with generalised abdominal tenderness but no evidence of focal peritonism.

Please see below for selected investigation results.

Observations: blood pressure 86 / 57 mmHg; heart rate 127 beats per minute; respiratory rate 28 per minute; O₂ saturations 100 % (room air); Temperature 37.1 °C.

Fingerpick blood glucose	38.2 mmol / L
Fingerpick blood ketones	8.7 mmol / L
Urea	12.5 mmol / L
Creatinine	123 micromol / L
Sodium	148 mmol / L
Potassium	3.7 mmol / L
Haemoglobin	156 g / dL
White cell count	14.3 x 10 ⁹ / microlitre
Neutrophils	11.3 x 10 ⁹ / microlitre
Platelets	453 x 10 ⁹ / microlitre

Arterial blood gas (room air)

pH	7.05
----	------

PaCO ₂	15 mmHg (reference 32-43)
PaO ₂	99 mmHg (reference 70-100)
Bicarbonate	12.3 mmol / L (reference 20.0-26.0)
Chloride	111 mmol / L (reference 99-108)
Lactate	7.5 mmol / L

What is the appropriate strategy for intravenous insulin treatment in this patient?

	Variable rate insulin infusion without initial bolus, converting to subcutaneous insulin once acidosis resolved
	Fixed rate insulin infusion without initial bolus, converting to subcutaneous insulin once patient is eating and drinking normally
	Fixed rate insulin infusion following initial bolus, converting to subcutaneous insulin once patient is eating and drinking normally
	Variable rate insulin infusion with initial bolus, converting to subcutaneous insulin once acidosis resolved
	Variable rate insulin infusion without initial bolus, converting to subcutaneous insulin once ketonaemia resolved

Question 56 of 79

A 66-year-old gentleman is reviewed in the General Medical Clinic with a 4-week history of polyuria, polydipsia, and generalised muscle weakness. He denies weight loss but does describe the presence of deep aching pains in his arms, legs, and lower back.

His past medical history is remarkable for hypertension, treated with amlodipine 5mg once daily and ramipril 7.5mg once daily. He also tells you that he has an 'antibody disorder' that requires no specific treatment but necessitates yearly follow-up at the Haematology Clinic.

Examination reveals a well-looking gentleman. His pulse is 74 bpm and his blood pressure is 132/63mmHg. There is no conjunctival pallor and his chest is clear to auscultation. His abdomen is soft and non-tender.

A series of investigations are requested:

Hb	132 g/l	Na ⁺	136 mmol/l	Bilirubin	17 µmol/l
Platelets	278 * 10 ⁹ /l	K ⁺	2.9 mmol/l	ALP	172 u/l
WBC	6.5 * 10 ⁹ /l	Cl ⁻	115 mmol/l	ALT	35 u/l
Neuts	3.8 * 10 ⁹ /l	Urea	5.2 mmol/l	γGT	39 u/l
Lymphs	1.8 * 10 ⁹ /l	Creatinine	87 µmol/l	Total Protein	92 g/l
Eosin	0.01 * 10 ⁹ /l			Albumin	40 g/l

Calcium	2.24 mmol/l
Adj. Calcium	2.24 mmol/l
Phosphate	0.38 mmol/l
Bicarbonate	18 mmol/l
Fasting glucose	4.9 mmol/l

Urine dip	Glucose ++ Protein ++
-----------	-----------------------

Question 59 of 79

A 71-year-old man presents to the emergency department having collapsed at home. On admission, he is confused and his daughter, who accompanied him to the emergency department states that she found him on the floor of the bathroom. There had not been any urinary incontinence or signs that he had bitten his tongue. He had been feeling hot and complaining of pain on urinating several days before the collapse. His past medical history includes rheumatoid arthritis, for which he takes long-term oral steroids. He is diagnosed in the emergency department as having urosepsis and is commenced on intravenous fluids and antibiotics.

What is the most appropriate other treatment for this patient?

	IV hydrocortisone
	IV hydrocortisone and fludrocortisone
	Oral prednisolone and fludrocortisone
	IV methylprednisolone and fludrocortisone
	Oral prednisolone

Question 60 of 79

A 28-year-old woman presents with symptoms of thyroid dysfunction over the past few weeks. She has also suffered from hypertension. Her thyroid gland is enlarged and tender to palpation. Her blood pressure is 128/82 mmHg, heart rate is 98 bpm, and she has a mild fever. There is tenderness over the anterior aspect of the thyroid gland.

Which of the following would be most likely to cause this presentation?

<input type="checkbox"/>	Erythema nodosum
<input type="checkbox"/>	Exophthalmos
<input type="checkbox"/>	Multiple small thyroid nodules
<input type="checkbox"/>	Positive anti-thyroid peroxidase antibodies
<input type="checkbox"/>	Reduced uptake on thyroid scintigraphy

Question 61 of 79

A 65-year-old gentleman presents with a 3 week history of general malaise, decreased oral intake and drowsiness. He has a past medical history of ischaemic heart disease, type 2 diabetes mellitus and gastritis. He lives alone with no carers and normally mobilises independently. A concerned neighbour went in to check on him after he was not seen for a few days. On examination his mouth is dry with reduced skin turgor. Heart sounds are normal, chest is clear, abdominal palpation reveals lower abdominal tenderness. ECG shows sinus tachycardia. Urine dip shows ketones +, glucose +++.

Blood tests show:

Hb	140 g/l	Na ⁺	150 mmol/l
Platelets	525 * 10 ⁹ /l	K ⁺	4.2 mmol/l
WBC	14 * 10 ⁹ /l	Urea	13 mmol/l
Neuts	10 * 10 ⁹ /l	Creatinine	160 µmol/l
Lymphs	2 * 10 ⁹ /l	CRP	56 mg/l
Eosin	0.5 * 10 ⁹ /l		

Venous blood gas shows no signs of acidosis. Formal blood glucose is phoned back as 40 mmol/L.

What is the most important initial treatment?

	Intravenous insulin
	Low molecular weight heparin
	Antibiotics
	Subcutaneous insulin
	Intravenous fluids

Question 62 of 79

You are seeing a 58-year-old man in clinic who has been referred by his GP with resistant hypertension despite treatment with ramipril, amlodipine, indapamide and bisoprolol. He looks comfortable at rest.

Observations are as follows: temperature 36.5°C, blood pressure 182/125 mmHg, heart rate 88/min, respiratory rate 16/min, saturations 97% on air

Investigations are as follows:

Na ⁺	148 mmol/l
K ⁺	2.9 mmol/l
Urea	6.5 mmol/l
Creatinine	92 µmol/l

Renin	Low
Aldosterone (supine)	High
Aldosterone (prolonged standing)	Increase from supine levels

Blood gases:

PaO ₂	11.2 kPa
PaCO ₂	5.2 kPa
pH	7.49
HCO ₃ ⁻	32 mmol/l
BE	+4

What is the single most likely diagnosis?

	Adrenal hyperplasia
	Conn's adenoma
	Malignant hypertension
	Phaeochromocytoma
	Renal artery stenosis

Question 63 of 79

A 72-year-old male was admitted drowsy and confused. His family describe a 4-day history of shortness of breath and a productive cough. His past medical history includes type 2 diabetes mellitus, hypertension and hypercholesterolaemia. He usually takes metformin 500 mg three times daily, gliclazide 80 mg twice daily, amlodipine 5 mg daily and simvastatin 40 mg nightly. On examination he is confused with dry mucous membranes, blood pressure of 100/50 mmHg, a pulse of 110/min, a temperature of 37.6 °C and a respiratory rate of 20/min. Course crepitations were found at the right base and his pulse was thready with a capillary refill of 3 seconds; jugular venous pressure was not visible. Capillary blood glucose was found to be 11.

A venous blood sample is taken:

Hb	129 g/l	Na ⁺	161 mmol/l
Platelets	204 * 10 ⁹ /l	K ⁺	4.9 mmol/l
WBC	13.1 * 10 ⁹ /l	Urea	15.2 mmol/l
Neuts	11.9 * 10 ⁹ /l	Creatinine	97 µmol/l
Glucose	56 mmol/l	eGFR	62 mg/l
Ketones	1.9 mmol/l	HbA1c	75 mmol/mol
pH	7.35	HCO ₃	20 mmol/mol

What treatment would you initiate first?

<input type="checkbox"/>	0.9% normal saline
<input type="checkbox"/>	0.45 % normal saline
<input type="checkbox"/>	Hartmann's solution
<input type="checkbox"/>	Intravenous insulin
<input type="checkbox"/>	5% dextrose

□ Question 64 of 79

An elderly male presents with a 2 week history of breathlessness. His past medical history includes diet-controlled type 2 diabetes, ischaemic heart disease, hypothyroidism and depression. His medication list includes levothyroxine, aspirin, simvastatin, ramipril, bisoprolol and citalopram. Observations on presentation to Emergency Department are as follows: respiratory rate 26/min, saturations 94% (on 4 litres oxygen via Venturi), heart rate 80 beats per minute, blood pressure 156/82 mmHg. Auscultation demonstrates crackles at the left base with no wheeze. The abdomen is soft and non-tender. There is no oedema peripherally.

Blood results on admission are provided below:

Hb	134 g/l
Platelets	$172 \times 10^9/l$
WBC	$13.3 \times 10^9/l$
Na ⁺	128 mmol/l
K ⁺	5.1 mmol/l
Urea	13 mmol/l
Creatinine	178 μ mol/l
Serum osmolality	220 mosm/kg
Urinary sodium	50 mEq/l

What is the most likely cause of hyponatraemia?

	Hypothyroidism
	Chronic kidney disease
	Addison's disease
	Salt-losing nephropathy

	Syndrome of inappropriate antidiuretic hormone (SIADH)

Question 66 of 79

A 62 year old male, recently emigrated from India, presents with 5 day history of feeling generally unwell. His niece, who has accompanied him to hospital, denies a history of recent productive cough, diarrhoea or vomiting or dysuria. Her uncle had been gradually increasingly malaised over the past 5 days and not eating and drinking well. He has no known past medical history. On examination, he has dry mucous membranes and cool peripheries, his JVP is +1cm above the angle of Louis. Heart sounds, chest and abdomen are unremarkable. Urine dip and chest radiograph are awaited. His blood tests are as follows:

WBC	16 * 10 ⁹ /l
Neutrophils	14.8 * 10 ⁹ /l

Na ⁺	152 mmol/l
K ⁺	3.7 mmol/l
Urea	22 mmol/l
Creatinine	208 µmol/l
CRP	38 mg/l
Glucose	38 mmol/l
Ketones	2.8 mmol/l

Arterial blood gases:

pH 7.31
PaO ₂ 20.2 kPa
PaCO ₂ 3.0 kPa
Bicarbonate 16 mmol/l
Lactate 4 mmol/l

What is the unifying diagnosis?

	Diabetic ketoacidosis (DKA)
	Lactic acidosis
	Hyperosmolar hyperglycaemic state (HHS)
	Urinary tract sepsis
	Chest sepsis

□ Question 67 of 79

A 78-year-old female attends the diabetes clinic. She has longstanding type 2 diabetes. Over the last few years she has become increasingly frail. Her main complaint is recurrent nausea and vomiting. Earlier this year she underwent endoscopy and gastric emptying studies which confirmed gastroparesis. She has since been started on metoclopramide which has had minimal effect on her symptoms. Her weight has decreased by 10% over the past year with a current BMI of 26 kg/m².

Her HbA1c today at the clinic is 44 IFCC mmol/l (6.2%) having been 60 IFCC mmol/l (7.6%) this time last year.

Her past medical history includes chronic kidney disease stage 3 and aortic stenosis.

Her current therapy is Humulin M3 22 units at breakfast and dinner, metformin 500mg BD, ramipril 5mg OD, bendroflumethiazide 2.5mg OD, aspirin 75 mg OD.

She lives alone and is still driving. She denies the need for carers, however, she has had 3 falls in the past month. She describes particular difficulty getting up in the morning and says her mood can often be low in the mornings.

She checks her blood sugar once daily in the morning with the following results.

Saturday	3.1 mmol/l
Sunday	4.0 mmol/l
Monday	4.1 mmol/l
Tuesday	3.2 mmol/l
Wednesday	14.6 mmol/l
Thursday	3.5 mmol/l
Friday	16.1 mmol/l

What is the correct step in the management of her diabetes?

Change Humulin M3 to a glucagon-like-peptide 1 receptor agonist

	Stop metformin
	Add sitagliptin
	Change Humulin M3 to 20 units in the morning and 10 units in the evening
	Change Humulin M3 to 30 units once daily

Overall score: **0%**

Question 68 of 79

A 56-year-old man with a high blood pressure has had his HbA1c and cholesterol checked.

His blood pressure today is 142/92 mmHg.

Na ⁺	142 mmol/L
K ⁺	4.6 mmol/L
Urea	5.2 mmol/L
Creatinine	88 µmol/L
Total cholesterol	5.2 mmol/L
HbA1c	45 mmol/mol (6.3%)

Fasting glucose:

<= 6.0 mmol/L

>= 6.0 mmol/L

Normal glycaemic control

Prediabetes

HbA1c is 42-47 mmol/mol (6.0-6.4%)
or
Fasting glucose 6.1-6.9 mmol/L

HbA1c:

<= 41 mmol/mol
(5.9%)

>= 48 mmol/mol

i.e. values equal to this or below are considered normal

i.e. values above this threshold are considered abnormal

His 10-year QRISK2 score is 7%. What is the most appropriate action following these results?

<input type="radio"/>	Start atorvastatin 20mg on alternate days
<input type="radio"/>	Arrange a fasting glucose sample
<input type="radio"/>	Diagnose type 2 diabetes mellitus
<input type="radio"/>	Increase the dose of ramipril
<input type="radio"/>	Add amlodipine 5mg od

□ Question 69 of 79

A 41-year-old woman is admitted to hospital with acute epigastric abdominal pain that radiates to her back. She has nausea but has not vomited. A diagnosis of acute pancreatitis is suspected and she is commenced on intravenous fluids. Her observations include a blood pressure of 129/72 mmHg, pulse of 88 bpm, and oxygen sats of 97%.

Blood tests are performed and reveal:

Hb	13.9 g/l
Platelets	194 * 10 ⁹ /l
WBC	8.6 * 10 ⁹ /l
Na ⁺	139 mmol/l
K ⁺	4.2 mmol/l
Urea	4.1 mmol/l
Creatinine	92 µmol/l
Bilirubin	10 µmol/l
ALP	39 u/l
ALT	34 u/l
γGT	44 u/l
Albumin	48 g/l
Triglycerides	12.1 mmol/l
HDL cholesterol	1.1 mmol/l
LDL cholesterol	3.5 mmol/l

What is the most appropriate treatment for this patients condition?

	Atorvastatin
	Fenofibrate
	Lovastatin
	Ezetimibe
	Alirocumab

□ Question 70 of 79

A 80-year-old patient was referred to Accident and Emergency after being found unresponsive in his home. He had just completed a course of antibiotics for a chest infection. He had not been seen for the preceding 36 hours. He had a past medical history of hypertension and type two diabetes.

His medication included Metformin, Gliclazide, Humulin M3 insulin twice a day, Ramipril and Bendroflumethiazide.

His initial examination revealed. Blood pressure 104/53, heart rate 103 beats per minute, respiratory rate 24 and oxygen saturations 90% on air. He had inspiratory crackles on his left lower lung zone. He had sunken eyes, capillary refill time of four seconds and no lower limb swelling. GCS 13 out of 15.

Initial blood tests;

Hb	11.0 g/dL
WCC	$21.4 \times 10^9/l$
Platelets	$189 \times 10^9/l$
CRP	340 mg/L
Na+	149 mmol/l
K+	4.4mmol/l
Ur	28 mmol/l
Cr	180 μ mol/l
Glucose	54mmol/l

ABG on air

pH	7.32
pCO2	3.7kPa
pO2	9kPa

HCO3	18 mmol/l
Lactate	2.4mmol/l

Urine dipstick analysis - ++ glucose, - WCC, - leucocytes, + ketones

The patient was treated with oxygen, intravenous antibiotics for a chest infection and prophylactic low molecular weight heparin. They were treated with the local diabetic ketoacidosis protocol with IV inulin sliding scale and IV fluids 5500ml in 24 hours.

His repeat bloods 12 hours later were;

Na+	132 mmol/l
K+	3.9 mmol/l
Ur	12 mmol/l
Cr	110 µmmol/l
Glucose	5 mmol/l
HCO3	24 mmol/l
Lactate	1.7 mmol/l
CRP	270mg/l

The patient developed a grand mal seizure. His Glasgow coma scale remained 10 an hour after the seizure.

What is the most likely cause of his neurological deterioration?

	Hypoglycaemia
	Intracranial venous sinus thrombosis
	Cerebral oedema
	Sepsis
	Renal failure

□ Question 70 of 79

A 80-year-old patient was referred to Accident and Emergency after being found unresponsive in his home. He had just completed a course of antibiotics for a chest infection. He had not been seen for the preceding 36 hours. He had a past medical history of hypertension and type two diabetes.

His medication included Metformin, Gliclazide, Humulin M3 insulin twice a day, Ramipril and Bendroflumethiazide.

His initial examination revealed. Blood pressure 104/53, heart rate 103 beats per minute, respiratory rate 24 and oxygen saturations 90% on air. He had inspiratory crackles on his left lower lung zone. He had sunken eyes, capillary refill time of four seconds and no lower limb swelling. GCS 13 out of 15.

Initial blood tests;

Hb	11.0 g/dL
WCC	$21.4 \times 10^9/l$
Platelets	$189 \times 10^9/l$
CRP	340 mg/L
Na+	149 mmol/l
K+	4.4mmol/l
Ur	28 mmol/l
Cr	180 μ mol/l
Glucose	54mmol/l

ABG on air

pH	7.32
pCO ₂	3.7kPa
pO ₂	9kPa

HCO3	18 mmol/l
Lactate	2.4mmol/l

Urine dipstick analysis - ++ glucose, - WCC, - leucocytes, + ketones

The patient was treated with oxygen, intravenous antibiotics for a chest infection and prophylactic low molecular weight heparin. They were treated with the local diabetic ketoacidosis protocol with IV insulin sliding scale and IV fluids 5500ml in 24 hours.

His repeat bloods 12 hours later were;

Na+	132 mmol/l
K+	3.9 mmol/l
Ur	12 mmol/l
Cr	110 µmmol/l
Glucose	5 mmol/l
HCO3	24 mmol/l
Lactate	1.7 mmol/l
CRP	270mg/l

The patient developed a grand mal seizure. His Glasgow coma scale remained 10 an hour after the seizure.

What is the most likely cause of his neurological deterioration?

	Hypoglycaemia
	Intracranial venous sinus thrombosis
	Cerebral oedema
	Sepsis
	Renal failure

□ Question 71 of 79

□ □

An 18-year-old male with no prior medical history is admitted to the resuscitation room of Emergency Department where you are asked to assess him. He is noted to be hypotensive, tachycardic and febrile. Further assessment highlights a widespread, non-blanching, purple rash. He is diagnosed with meningococcal septicaemia and is treated appropriately. Nevertheless, his condition deteriorates further when he also develops Waterhouse-Friderichsen syndrome. Which of the following sets of blood results would be most consistent with his condition at this point?

	Na+ 147mmol/L, K+ 5.8mmol/L, Glucose 7.5mmol/L
	Na+ 147mmol/L, K+ 3.0mmol/L, Glucose 2.0mmol/L
	Na+ 129mmol/L, K+ 5.8mmol/L, Glucose 2.0mmol/L
	Na+ 147mmol/L, K+ 5.8mmol/L, Glucose 11.5mmol/L
	Na+ 129mmol/L, K+ 5.8mmol/L, Glucose 11.5mmol/L

□ Question 72 of 79

A 32-year-old alcoholic presents with abdominal pain and vomiting. His amylase is 1200 U/l and he is being treated for acute pancreatitis. You are called to see him as the nursing staff report the patient is becoming restless. He complains of numbness around his mouth and appears to be in some discomfort.

Your foundation year 2 colleague notes this morning's blood results:

Adjusted calcium	1.8mmol/l
Na ⁺	136 mmol/l
K ⁺	3.7 mmol/l
Urea	6.9 mmol/l
Creatinine	81 µmol/l

What's the next step in management?

	Parathyroid hormone
	Oral calcium supplementation
	Calcitonin assay
	Intravenous 10% calcium gluconate
	Serum magnesium

□ Question 73 of 79

A 25 year old woman presents to the endocrinology clinic. She is concerned because her father had a 'brain tumour' removed 2 years ago and has now been told he has another tumour in his abdomen after going to his doctor with reflux and indigestion. He has been told it might be a genetic problem and is awaiting testing. She is concerned she might also have the condition and so her GP has referred her to the clinic.

She is currently asymptomatic.

On examination there is no abnormality on the cardiovascular, respiratory, abdominal or neurological examinations.

The doctor explain that the most appropriate person to see would be the geneticist to whom her father has been referred. He asks her to obtain the details if her father is willing to provide them and says that he will refer her. In the meaning time he offers to carry out some screening blood tests.

Given the likely underlying diagnosis, which of the following is most likely to be abnormal?

	Cortisol
	Fasting glucose
	Parathyroid hormone
	Prolactin
	Thyroid stimulating hormone

Dashboard

A 34-year-old man of ethnic Indian origin is reviewed in endocrinology clinic. He has type 1 diabetes. He has a twice-daily mixed insulin regime but has poor diabetic control with elevated HbA1c and high blood glucose. He wants to improve his diabetic control but is concerned about increasing his insulin dose or frequency as he is already overweight with a body mass index (BMI) of 29kg/m².

Apart from increasing insulin, are there any other medical management options to better control his diabetes?

	No further medical treatment
	Metformin
	Gliclazide
	Acarbose
	Pioglitazone

A 28 year old lady has noticed over the last year that she does not tolerate cold weather well. She is fatigued and her partner notices that she is also low in mood despite having no obvious triggers. Physical examination is unremarkable. Her electrocardiogram (ECG) demonstrates a sinus rhythm at 43 beats per minute. She has a background of type 1 diabetes mellitus for which she takes insulin. She also has coeliac disease. Her blood results are shown below:

Hb	136 g/dl
MCV	103 fL

Na	133 mmol/l
K	4 mmol/l
Urea	3.5 mmol/l
Creatinine	70 µmol/l

Glycosylated haemoglobin (HbA1c)	51 mmol/mol (6.8%)
TSH	9.2 mIU/L (reference range 0.3-4.0 mIU/L)
T3	2 pmol/L (reference range 3-9 pmol/L)
T4	5 pmol/L (reference range 9-25 pmol/L)

What is the next best step in her management?

	Commence levothyroxine
	Commence carbimazole
	Ultrasound scan thyroid
	MRI pituitary

	Short synacthen test

□ Question 3 of 204

You are asked to see a young man on the gastroenterology ward because of increasing abdominal discomfort. Looking through his notes you notice that he is a patient with known alcoholic cirrhosis and that he's been admitted with worsening ascites (which the consultant has described as grade 3/3 or large). The patient's recent laboratory results are as follows:

Na ⁺	133 mmol/l
K ⁺	4.1 mmol/l
Urea	1.2 mmol/l
Creatinine	64 µmol/l
Bilirubin	23 µmol/l
ALP	151 u/l
ALT	7 u/l
Albumin	26 g/l

Ascitic Tap:

WCC count	300cells/mm ²
Differential	70% polymorphs
Albumin	14

Talking to the patient it is obvious that he's uncomfortable with this ascites, and on examination his abdomen is significantly distended and tense. From his drug chart you can see that he is currently taking spironolactone 50mg twice daily and is currently on Pabrinex and chlordiazepoxide reducing regimen currently on 30mg four times daily.

What is the next step in managing his ascites?

--	--

	Fluid restrict him to 1L
	Increase spironolactone to 100mg BD
	Add furosemide 40mg BD to his current diuretic regimen
	Therapeutic aspiration
	Large volume abdominal paracentesis

Dashboard

Overall score: **0%**

□ Question 4 of 204

□ □

A 63-year-old man is referred for an OGD after a 5 month history of epigastric pain after eating. He is also suffering from significant reflux and dyspepsia. His OGD shows 2 duodenal ulcers, and a CLO test taken at the time is positive. He also suffers from hypertension and type 2 diabetes, which are controlled with amlodipine and metformin. He is allergic to penicillin.

What is the current gold standard treatment for *H. pylori* eradication for this patient?

	Pantoprazole, metronidazole and levofloxacin
	Amoxicillin, clarithromycin and omeprazole
	Omeprazole, clarithromycin and metronidazole
	Bismuth, tetracycline, metronidazole, omeprazole
	Clarithromycin, levofloxacin and lansoprazole

□ Question 5 of 204

A 55-year-old male was referred to the gastroenterology clinic after presenting with a 3-month history of yellow discolouration of his skin. He stated that his skin had become rather itchy, and in addition, his urine had become darker. After following the 'Abnormal Liver Function Test Protocol' the GP referred the patient to the clinic, having not been able to identify a cause of his symptoms. The gentleman was otherwise well in himself, denying the presence of abdominal pain, bloating or weight loss. He smoked 10 cigarettes per day and consumed 42 units of alcohol per week. His past medical history comprised diet controlled type 2 diabetes mellitus, hypertension, hypercholesterolaemia and asthma for which he was prescribed amlodipine 5mg OD, simvastatin 40mg ON, Seretide 125 BD and salbutamol PRN. Of note, he has hospitalised 4 months ago with pneumonia and was treated with 2 days of intravenous co-amoxiclav, before being switched over to oral co-amoxiclav for a further five days.

Examination revealed the presence of a well male, with a temperature of 37.1 C, heart rate of 72 bpm, respiratory rate of 16 and blood pressure of 152/76 mmHg. He appeared mildly jaundiced but other than this examination of his gastrointestinal system was unremarkable. Examination of his cardiovascular and respiratory systems was otherwise also unremarkable.

Initial investigations revealed:

Hb	139 g/l
Platelets	222 * 10 ⁹ /l
WBC	6.1 * 10 ⁹ /l
INR	1.0

HbA1c	52 mmol/mol
Bilirubin	62 µmol/l
ALP	112 u/l
AST	24 u/l
ALT	26 u/l

γGT	64 u/l
Albumin	38 g/l
Protein	78 g/l
Adj calcium	2.32 mmol/l

Anti nuclear antibody	negative
p-ANCA	negative
c-ANCA	negative
Anti-mitochondrial antibodies	negative
Anti smooth muscle antibodies	negative
Anti liver and kidney antibodies	negative
Serum electrophoresis	normal appearance

USS liver, abdomen and pancreas: normal appearance of all intraabdominal organs including that of liver and pancreas. Normal appearance of the biliary tree.

What is the most likely diagnosis?

	Cholestasis secondary to co-amoxiclav
	Non alcoholic steatohepatitis (NASH)
	Alcoholic hepatitis
	Primary biliary cirrhosis
	Primary sclerosing cholangitis

Dashboard

□ Question 6 of 204

A 78 year old woman is admitted to the acute medical unit due to shortness of breath. She had been living alone at home for the last 3 years since her husband died. In the last 6 months she was struggling to manage due to fatigue, nausea and progressive breathlessness. She had noticed that her clothing was feeling tighter but could not understand why as she had reduced appetite and was eating less than normal. She is a non smoker and drank 1-2 bottles of wine per week since the death of her husband.

She has a history of ischaemic heart disease following an acute myocardial infarction two years previously. An echocardiogram 6 months after the acute event showed a mildly dilated left ventricle with good overall function (ejection fraction 45-55%) and mild aortic stenosis. Past medical history also includes a left mastectomy 17 years ago for a small breast carcinoma. Lymph node sampling at the time showed clear nodes so axillary clearance was not carried out. She has been discharged from follow up at the breast clinic.

On examination she is afebrile with no evidence of clubbing or splinter haemorrhages nor any spider naevi. Her chest was clear to auscultation with dullness to percussion at both bases. The cardiac apex was non-displaced and heart sounds were normal with an additional ejection systolic murmur. Her abdomen appeared distended with large volume ascites but was soft and non tender. Bowel sounds were normal.

Bloods showed the following:

Haemoglobin	101 g/L	Sodium	134 mmol/L
Platelets	159 x10 ⁹ /L	Potassium	3.8 mmol/L
White cell count	9.0 x10 ⁹ /L	Urea	3.5 mmol/L
Neutrophils	3.5 x10 ⁹ /L	Creatinine	67 micromol/L
ESR	21 mm/h	Albumin	31 g/L
CRP	34 mg/L	Bilirubin	7 micromol/L
ALT	29 iu/L		
Alkaline Phosphatase	51 iu/L		

Ascitic fluid analysis:

Fluid albumin	22 g/L
Fluid glucose	4.2
Fluid gram stain	negative

Which of the following is the most likely cause of her ascites?

	Alcoholic hepatitis
	Heart failure
	Peritoneal metastases from colon cancer
	Portal vein thrombosis
	Myxoedema due to hypothyroidism

□ Question 7 of 204

□ □

You are called to see a 35-year-old man on the Acute Medical Unit who is having a seizure.

He was admitted 2 days ago having presented acutely agitated to the Emergency Department. He gave a 10-year history of alcohol overuse and at that time had not had an alcoholic drink in 24 hours following an argument with his girlfriend where he vowed to give up alcohol. Prior to this he had been drinking 4-6 litres of cider per day plus additional spirits in variable amounts. He was admitted for detox and prescribed chlordiazepoxide, pabrinex and fluids. He has no other past medical history.

Nursing staff inform you that the patient has had no other seizures on this admission and has been eating and drinking small amounts today. However, he has been complaining of all over body pain and became confused 2-3 hours ago. The seizure is generalised tonic-clonic and self terminates after 3 minutes.

On examination post-seizure the patient is drowsy but responding to voice. His saturations are 100% on 15 litres oxygen via non-rebreathe mask and his temperature is 37.2 °C. His heart rate is 110 beats per minute and blood pressure is 126/72 mmHg. His chest is clear, abdomen soft and non-tender and there is no focal neurology.

Repeat blood tests and arterial blood gas are taken.

Which electrolyte abnormality is most likely to have caused his seizure?

	Hypocalcaemia
	Hypoglycaemia
	Hypokalaemia
	Hypomagnesaemia
	Hypophosphataemia

□ Question 7 of 204

□ Question 8 of 204

A 48 year-old woman attends the outpatient department with a four month history of myalgia, itching and malaise. She has no past medical history and no relevant family history. Apart from taking antihistamines for the itching, she takes no regular medication and has a 10 pack year history. She also drinks on average 5-10 units of alcohol per week.

Examination reveals mild jaundice, 3 spider naevi on her torso and 4 spider naevi on her face.

Blood tests reveal:

Bilirubin	132 μ mol/l
ALP	225 u/l
ALT	192 u/l
γ GT	84 u/l
Albumin	34 g/l
Antismooth muscle antibodies	Positive
Antinuclear antibodies	Positive
HBsAg	Negative
HBsAb	Positive
HBcAb	Negative

What is the most likely diagnosis?

□ Question 10 of 204

□ □

A 35-year-old woman presents to hospital with a three-day history of acute abdominal pain and distension. Her past medical history includes asthma, coeliac disease and an unprovoked deep vein thrombosis in her left leg a year ago. Her medications include Symbicort 400/12 2 puffs BD and salbutamol PRN. She does not smoke and drinks approximately 12 units of alcohol a week. She works as a secretary in a legal firm. Her parents both suffer from type 2 diabetes mellitus.

On examination, her temperature is 37.7°C, pulse rate is 110 beats per minute and blood pressure is 130/80 mmHg. There is evidence of icterus in her sclera. Inspection of her abdomen reveals gross distension. There is hepatomegaly on palpation and shifting dullness on percussion. There is marked tenderness on palpation of the right upper quadrant of her abdomen.

Her blood tests show:

Hb	100 g/l	Na ⁺	138 mmol/l	Bilirubin	63 µmol/l
Platelets	740 * 10 ⁹ /l	K ⁺	5.2 mmol/l	ALP	295 u/l
WBC	14.2 * 10 ⁹ /l	Urea	5.1 mmol/l	ALT	230 u/l
Neuts	9.5 * 10 ⁹ /l	Creatinine	89 µmol/l	γGT	210 u/l
Lymphs	0.7 * 10 ⁹ /l			Albumin	26 g/l
INR	1.5	CRP	93 mg/L	Amylase	173 U/L

What is the most likely diagnosis?

	Budd-Chiari syndrome
	Hepatic abscess
	Portal vein thrombosis
	Acute pancreatitis

Dashboard

□ Question 13 of 204

□ □

A 58-year-old man known to homeless services is brought to the emergency department by ambulance. He has been unwell with fevers and abdominal pain. He also reports increasing abdominal distension. His past medical history is significant for drug and alcohol dependency with hepatitic C and cirrhotic liver disease. He does not engage with medical services and takes no regular medications. An ascitic tap is performed that confirmed spontaneous bacterial peritonitis. He is admitted for IV antibiotics. You are called to see him by the nursing staff who report that his is agitated and restless during the night and drowsy during the day. On examination, he is unaware of the time or his current location and demonstrates asterixis.

Given the most likely diagnosis, what medical therapy should be instituted?

	Lactulose - aiming for 3 stools/day, ceased after improvement
	Rifaximin - ceased after improvement
	Lactulose - aiming for 3 stools/day, continued after improvement
	Lactulose and rifaximin - continued after improvement
	Lactulose and rifaximin - ceased after improvement

□ Question 14 of 204

A 64 year-old woman is admitted to hospital with profuse, watery diarrhoea and abdominal cramps. The diarrhoea and cramps began 3 days ago and there is no reported blood or mucous in the stools. The patient also reports feeling hot, although she states this is probably due to the menopause. She had an episode of diarrhoea 2 weeks ago, which resolved on its own after five days and she blames these last two episodes on her lifestyle of eating regular takeaways due to her busy job and irregular shifts as a paramedic. Her past medical history includes asthma and hayfever. Her regular medications include ramipril and beclomethasone inhaler. She has a thirty pack year history and currently drinks a bottle of red wine per night.

Blood tests reveal:

Na ⁺	134 mmol/l
K ⁺	3.3 mmol/l
Urea	5.9 mmol/l
Creatinine	105 µmol/l
Bilirubin	6 µmol/l
ALP	35 u/l
ALT	242 u/l
γGT	70 u/l
Albumin	38 g/l

On examination, the patient has heart sounds 1 and 2 present with no added sounds. Lung fields are clear and abdominal exam reveals non-tender hepatomegaly.

What is the most likely diagnosis?

	Alcoholic liver disease
	Thyrotoxicosis

	Infective gastroenteritis
	Pseudomembranous colitis
	Carcinoid syndrome

□ □

A 50-year-old male with a long history of cirrhosis secondary to chronic hepatitis C is brought to the emergency department by his partner with a 2-day history of increasing confusion.

He is drowsy but is rousable to voice. He is able to obey commands but is not oriented to where he is. Further examination revealed significant hepatic flap, multiple spider naevi on the torso, and mild abdominal distension with shifting dullness.

He is afebrile and his partner denies any history of recent infection.

His blood sugar level is 6.8 mmol/L

Which of the following should be started next?

	Intravenous dextrose
	Regular intravenous haloperidol
	Oral rifaximin
	Intravenous midazolam
	Regular oral lactulose

Question 20 of 204

□ □

A 32-year-old pregnant woman presents to the GP with jaundice and itchy skin for the past 2 weeks. She claims that is a lot worse during this pregnancy compared to her last one. History reveals that she is currently 30 weeks pregnant with no complications up until presentation. On examination, the only notable findings are mild jaundice seen in the sclerae, as well as excoriations around the umbilicus and flanks. She denies any tenderness in her abdomen during the examination. Blood tests show the following:

ALT	206 U/L
AST	159 U/L
ALP	796 umol/l
GGT	397 U/L
Bilirubin (direct)	56 umol/L
Bile salts	34 umol/L

Bile salts reference range	0 - 14 umol/L
----------------------------	---------------

What is the most likely diagnosis?

	Obstetric cholestasis
	Budd-Chiari syndrome
	Acute hepatitis
	HELLP syndrome
	Acute fatty liver of pregnancy

Overall score: **0%**

Question 21 of 204

A 53 year old presents with recurrent episodes of dysphagia to solids and fluids, resolving completely after 2 weeks. This is his third episode in 4 months. He reports weight loss of over two stones since the problem started and is fearful of further oral intake in case he vomits up any food he tries to ingest. He denies haematemesis or malaena. His past medical history includes angina, for which he currently takes minimal doses of GTN. He stopped taking isosorbide mononitrate prescribed to him by his cardiologist as it caused unbearable headaches. His mother died of pancreatic cancer and his uncle recently had an anterior resection for sigmoid colonic carcinoma. His GP initially improved his swallowing symptoms with nifedipine but they now have no effect. An OGD was unable to pass an obstruction at the proximal oesophagus. A barium swallow demonstrated a 'corkscrew appearance'. What is the next management?

	Change ISMN to diltiazem
	Oral imipramine
	Percutaneous endoscopic gastrostomy (PEG) tube insertion
	Sildenafil
	Widespread pneumatic dilation

Question 22 of 204

□ □

A 40-year-old man is referred by his GP to the outpatient department with a 4 month history of tiredness and itching. He currently sleeps excessively during the daytime and reports he is having trouble concentrating at work, where he is an auditor. The itching becomes worse when he is in hotter climates and if he sleeps with a blanket over him. His past medical history includes asthma and dry eyes. His regular medications include beclometasone and antihistamine that he takes for the itching. He is not allergic to any medication and there is no family history of any known conditions. He does not smoke and drinks 5-10 units of alcohol per week.

Examination reveals mild jaundice of the sclera and scratch marks over his upper torso and arms. On examination of his abdomen, he has a slightly enlarged spleen and liver, both by 1cm.

Blood tests reveal raised bilirubin and alkaline phosphatase (ALP). Autoantibody screening reveals antimitochondrial antibodies (AMA) and antinuclear bodies (ANA) both being present.

What is the most appropriate management to help control his symptoms?

	Hydroxyzine
	Cetirizine Hydrochloride
	Ursodeoxycholic acid
	Fexofenadine
	Corticosteroid therapy

□ Question 23 of 204

A 35-year-old woman attends gastroenterology clinic following a referral from her general practitioner. The patient is suffering from ongoing gastrointestinal symptoms following a recent diagnosis of giardiasis, despite receiving appropriate first line treatment. The patient reports a 3-month history of variable bowel habit, consisting of periods of normal motions interspersed with episodes of frequent diarrhoea. During the course of her illness, the patient reports having lost approximately 7 kg in weight. The patient denied every experiencing fever or bloody diarrhoea, but did report unusual episodes of burping with an unpleasant taste, described by the patient as tasting like 'rotten eggs'.

After her initial symptoms, the patient attended her GP, with a subsequent stool microscopy test demonstrating evidence of infection with *Giardia lamblia*. The patient had not undertaken any recent overseas travel but was employed as a nursery nurse, which was suspected of being the source of her infection. Her employer had moved the patient to a different job role, not including direct contact with children after the patient disclosed her condition.

After the diagnosis of giardiasis, the patient was treated with a 5-day course of metronidazole consistent with British National Formulary guidelines. Following treatment, the patient reported some improvement but had not gained full resolution of her symptoms.

The patient was normally fit and well and her only significant past medical history was a salpingectomy performed 5 years previously due to an ectopic pregnancy. She had never previously experienced problematic gastrointestinal symptoms. The patient took no regular medications and had no known drug allergies.

Examination of the patient's abdomen was unremarkable and she appeared to be in generally good physical condition. A urinary pregnancy test was negative.

Following her review in the clinic, a decision was made to prescribe the patient a single dose of tinidazole as a second-line treatment for giardiasis. What advice should be given to the patient alongside this treatment?

	Avoid consuming legumes for 2-6 weeks
	Avoid consuming dairy products for 2-6 weeks
	Avoid consuming eggs for 2-6 weeks
	Her ongoing symptoms are likely secondary to irritable bowel syndrome not giardiasis

Avoid consuming gluten for 2-6 weeks

□ Question 24 of 204

A 47-year-old lady is admitted to hospital with a 5-day history of abdominal pain, fever, anorexia, and malaise. Her past medical history is remarkable for depression and there is a long history of alcohol excess.

On examination, the patient is jaundiced and unwell. Her temperature is 37.9°C, her pulse is 106bpm and her blood pressure is 97/61mmHg. Her chest is clear but her abdomen is distended. There is right upper quadrant tenderness on palpation of the abdomen without overt peritonism, and evidence of shifting dullness on percussion. A hepatic bruit is also present.

Her bloods are as follows:

Hb	99 g/l	Na ⁺	128 mmol/l	Bilirubin	92 µmol/l
Platelets	113 * 10 ⁹ /l	K ⁺	4.8 mmol/l	ALP	138 u/l
WBC	11.2 * 10 ⁹ /l	Urea	7.9 mmol/l	AST	168 u/l
Neuts	8.7 * 10 ⁹ /l	Creatinine	103 µmol/l	ALT	82 u/l
Lymphs	2.3 * 10 ⁹ /l			γGT	208 u/l
INR	1.8			Albumin	28 g/l

She is started on vitamin supplementation, nutritional support, and oral prednisone.

After 7 days the patient is re-assessed. She remains significantly jaundiced and has become progressively more confused. Her repeat blood tests show:

Na ⁺	131 mmol/l	Bilirubin	127 µmol/l
K ⁺	4.2 mmol/l	ALP	172 u/l
Urea	11.2 mmol/l	ALT	76 u/l
Creatinine	134 µmol/l	γGT	168 u/l
INR	2.3	Albumin	21 g/l

Her Lille score is calculated as 0.52. How should her treatment be altered?

	Discontinue prednisolone and add etanercept
	Discontinue prednisolone and add pentoxifylline
	Continue prednisolone and add pentoxifylline
	Discontinue prednisolone and continue supportive care
	Palliate

□ Question 31 of 204

A 26-year-old man comes to the outpatient clinic. He describes a 2-month history of weight loss, cramping lower abdominal pain with increasing stool frequency. His stools often have blood and mucus in them and occasionally he passes pure blood with no faeces. He is normally fit and well and takes no regular medications. On examination, he has a low-grade fever at 37.5 and pale. His abdomen is soft but tender across the lower half. His bloods checked by the GP earlier in the week are as follows:

Hb	110 g/l
Platelets	400 * 10 ⁹ /l
WBC	12.0 * 10 ⁹ /l
Neuts	9.0 * 10 ⁹ /l

Na ⁺	139 mmol/l
K ⁺	4.5 mmol/l
Urea	4.0 mmol/l
Creatinine	89 µmol/l
CRP	60 mg/L (<10)

Bilirubin	8 µmol/l
ALP	78 u/l
ALT	34 u/l
Albumin	36 g/l

Stool cultures sent by the GP are negative.

He is admitted the same day for a flexible sigmoidoscopy which shows mild colitis extending to the mid-descending colon. Biopsies are taken which show mild colitis but of indeterminate cause.

He is transferred to the ward and started on IV hydrocortisone 100mg QDS and he clinically improves and is started on regular mesalazine. He is found to be positive for anti-Saccharomyces cerevisiae antibodies but negative for pANCA. What is the likely cause of his colitis?

	Ulcerative colitis
	Microscopic colitis
	<i>C.difficile</i> infection
	Behcet's disease
	Crohn's disease

□ Question 32 of 204

A 37-year-old woman who is 32 weeks pregnant presents with malaise, headaches and vomiting. She is admitted to the obstetrics ward after a routine blood pressure measurement was 190/95mmHg. Examination reveals right upper quadrant abdominal pain and brisk tendon reflexes. The following blood tests are shown:

Hb	85 g/l
WBC	$6 \times 10^9/l$
Platelets	$89 \times 10^9/l$

Bilirubin	2.8 $\mu\text{mol/l}$
ALP	215 u/l
ALT	260 u/l
γGT	72 u/l
LDH	846 u/l

A peripheral blood film is also taken which shows polychromasia and schistocytes.

What is the most likely diagnosis?

	Obstetric cholestasis
	HELLP syndrome
	Eclampsia
	Gestational hypertension
	Acute viral hepatitis

□ Question 33 of 204

An 80 year-old man presents with a 3 month history of generalised abdominal pain and a change in bowel habit. The abdominal pain is colicky in nature and does not radiate anywhere. He also reports increasing distension of his abdomen and 2 episodes of blood in the rectum several weeks ago. He has recently undergone colonoscopy, which did not reveal anything abnormal. His past medical history includes diabetes type 2 and a heart attack two years ago, for which he needed three stents. His mother died of a stroke when he was 60 and his father died of a heart attack at the age of 55. His current medications include ramipril, aspirin, atenolol, atorvastatin and metformin. He has a 40 year pack history and drinks on average 15 units per day.

Blood tests reveal:

Hb	12.0 g/dL
Mean corpuscular volume (MCV)	80 fl
Platelets	$198 \times 10^9/l$
WBC	$13.1 \times 10^9/l$
Na ⁺	132 mmol/l
K ⁺	5.1 mmol/l
Urea	9.0 mmol/l
Creatinine	145 μ mol/l

Other than an abdominal x-ray, what is the most appropriate investigation?

	Contrast-enhanced computed tomography (CT) of the abdomen with angiography
	Colonoscopy
	Endoscopy
	MRI of the abdomen

	Angiography

Question 34 of 204

A 32-year-old man presents with loose stools or diarrhoea on all occasions for almost a year now, associated with intermittent, mild, generalised, crampy abdominal pain that has no obvious triggers. He has lost three stone (19 kilogrammes) in weight over the year despite not trying to. For nearly 10 years he has had episodes of arthralgia and fever which he has never thought to consult about. He once travelled to Gambia on his gap-year aged 18 and recalls several mosquito bites. He took full malaria prophylaxis as directed for the trip. His partner notices that as of the last 2-3 years he has had lapses in memory and is performing badly in his day-to-day tasks at work as a stoke broker such that he has now been made redundant. This has encouraged him to consult. On clinical examination, you find an emaciated gentleman with mild polyarthralgia and an ataxic gait. His Mini-Mental State Examination (MMSE) score is 22/30. Below are some of his blood test results:

Hb	90 g/l
Platelets	$300 \times 10^9/l$
WBC	$10 \times 10^9/l$
MCV	70 fL
Ferritin	8 micrograms/l

Na ⁺	140 mmol/l
K ⁺	2.9 mmol/l
Urea	11 mmol/l
Creatinine	110 μ mol/l

Calcium	1.9 mmol/l
Magnesium	0.5 mmol/l
Rheumatoid factor	negative

You organise a small bowel biopsy. What abnormality is the histology likely to show?

	Increased increased intraepithelial lymphocytes with villous atrophy and crypt Hyperplasia
	Deposition of macrophages containing PAS-positive granules within villi
	Transmural inflammation with multiple lymphoid aggregates
	Adenocarcinoma
	Carcinoid tumour cells with trabecular cell arrangements

□ Question 35 of 204

A 75-year-old man was admitted to hospital with a three-day history of right sided abdominal pain and vomiting. He has a history of ischaemic heart disease, chronic obstructive pulmonary disease and peripheral vascular disease.

On examination, he appears unwell. His temperature is 38.5°C, heart rate is 120 beats per minute, respiratory rate is 24 breaths per minute and blood pressure is 90/60 mmHg. He appears jaundiced. Examination of his abdomen reveals tenderness over the right upper quadrant on palpation.

Blood tests show:

Hb	115 g/l	Na ⁺	146 mmol/l	Bilirubin	225 µmol/l
Platelets	650 * 10 ⁹ /l	K ⁺	5.8 mmol/l	ALP	894 u/l
WBC	24.3 * 10 ⁹ /l	Urea	10.5 mmol/l	ALT	160 u/l
Neuts	20.5 * 10 ⁹ /l	Creatinine	190 µmol/l	γGT	279 u/l
CRP	348 mg/L			Albumin	27 g/l

An urgent ultrasound of his abdomen reveals sludge in his gallbladder and a dilated common bile duct at 13mm. His spleen and kidneys appear normal. He was fluid resuscitated and started on piperacillin-tazobactam after blood cultures were taken. After 6 hours of treatment, his blood pressure improves to 130/70 mmHg, his heart rate has decreased to 95 beats per minute and he is passing 50 millilitres of urine an hour.

What is the next appropriate management for this patient?

	Watch and wait
	Endoscopic retrograde cholangiopancreatography
	Percutaneous transhepatic cholangiogram
	Urgent cholecystectomy

	Refer to intensive care

□ Question 38 of 204

A 38 year-old nulliparous woman, who is at 35 weeks gestation, presents with a 10-hour history of fatigues, nausea and vomiting. She has not eaten for the past 24 hours and says that she feels a little dizzy. She describes no blood in her vomit and has had no recent changes in her bowel habit. She has no past medical history of note and she does not currently take any regular medication. She has no family history of note and does not smoke or drink any alcohol.

On examination she appears to be very anxious and abdominal exam reveals right upper quadrant and epigastric pain on deep palpation. There is no organomegaly and bowel sounds are present. The baby is moving normal.

She has a temperature of 37.5°C, heart rate of 85 beats per minute, blood pressure of 135/80mmHg, oxygen saturation of 99% and a respiratory rate of 18 breaths per minute.

Blood tests reveal:

Hb	10.5 g/dL
Platelets	82 * 10 ⁹ /l
WBC	12.9 * 10 ⁹ /l
Na ⁺	134 mmol/l
K ⁺	3.9 mmol/l
Urea	7.2 mmol/l
Creatinine	95 µmol/l
CRP	20 mg/l
ESR	8 mm/hr
Bilirubin	90 µmol/l
ALP	140 u/l
ALT	431 u/l
γGT	45 u/l

Albumin	30 g/l
Prothrombin time (PT)	23 seconds

What is the most likely diagnosis?

	Ascending cholangitis
	Intrahepatic cholestasis of pregnancy
	Fatty liver of pregnancy
	Infectious gastroenteritis
	Hyperemesis gravidarum

□ Question 39 of 204

A 38 year-old man, who has a job as a pastry chef is referred by his GP with pale, offensive stools and weight loss of 5 kg over the last two months. He has a past medical history of episodic acid reflux disease for which he was recently prescribed omeprazole. He drinks several glasses of wine a day and has a five year pack history.

Blood tests reveal:

Hb	9.9 g/dL
Mean corpuscular volume (MCV)	115 fL
Platelets	$280 \times 10^9/L$
WBC	$7.1 \times 10^9/L$
Na ⁺	136 mmol/L
K ⁺	4.0 mmol/L
Urea	3.2 mmol/L
Creatinine	52 $\mu\text{mol/L}$
Bilirubin	15 $\mu\text{mol/L}$
ALP	140 u/L
ALT	50 u/L
γGT	210 u/L
Albumin	39 g/L
Vitamin B12	120 ng/L
Faecal elastase	98 g/g (normal > 200)

What is the most appropriate next investigation?

--	--

	Abdominal ultrasound scan
	Liver biopsy
	Magnetic resonance cholangiopancreatography (MRCP)

□ Question 40 of 204

□ □

A 84-year-old lady is admitted to the Emergency Department from her nursing home with diarrhoea, abdominal pain and fever. Her symptoms started around 2 days ago and have been getting progressively worse. She is now opening her bowels every other hour and is complaining of severe 'cramp' in her lower abdomen. Her past medical history includes hypertension, ischaemic heart disease, hypothyroidism and recent treatment for suspected pyelonephritis.

On examination she is diffusely tender across the lower abdomen. Her pulse is 90/min, blood pressure 100/60 mmHg and temperature 37.4°C.

Bloods show the following:

Hb	11.1 g/dl	Na ⁺	144 mmol/l
Platelets	365 * 10 ⁹ /l	K ⁺	4.6 mmol/l
WBC	25.2 * 10 ⁹ /l	Urea	10.6 mmol/l
		Creatinine	99 µmol/l
		CRP	86 mg/l

The surgeons request an abdominal film and later a CT abdomen:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Perinephric abscess
	Ischaemic colitis
	Acute diverticulitis
	Metastatic colorectal cancer
	<i>Clostridium difficile</i> colitis

A 19-year-old man presented to the Emergency Department with frequent, bloody diarrhoea. He reported increasing stool frequency over the past two weeks and at presentation was opening his bowels 20 times per day including nocturnal episodes. He also reported feeling increasingly tired and lethargy with some cramping abdominal pains. The patient had no previous past medical history and took no regular medications. Past medical history was unremarkable and the patient took no regular medications. He worked as a trainee plumber, drank alcohol moderately and did not smoke.

Examination demonstrated some diffuse lower abdominal tenderness but with no signs of peritonism. Blood tests at presentation demonstrated anaemia (Hb 105 g / dL) and raised inflammatory markers (ESR 85 mm / h). Initial impression was of an acute severe colitis and treatment with intravenous hydrocortisone and oral 5-aminosalicylates was initiated. A limited flexible sigmoidoscopy demonstrated severe proctitis with inflammation extending beyond the limits of the study at the mid-sigmoid colon. Plain film imaging of chest and abdomen was unremarkable.

A summary of the patients observations and investigations at day 4 from presentation is given below.

- Stool chart: 12 large volume bloody type 7 stools over previous 24 hours
- Blood pressure: 105 / 67 mmHg
- Heart rate: 98 beats / min
- Respiratory rate: 19 breaths / min
- Temperature: 36.5°C

Haemoglobin	99 g / dL
White cell count	15 * 10 ⁹ /l
Neutrophils	13.2 * 10 ⁹ /l
Platelets	421 * 10 ⁹ /l
Urea	6.8 mmol / L
Creatinine	87 micromol / L
Erythrocyte sedimentation rate	67 mm / h

What is the next step in management?

	Infliximab
	Azathioprine
	Colectomy
	Add topical 5-aminosalicylates
	Rituximab

Question 43 of 204

□ □

A 23 year old female presents with a 4 month history of diarrhoea with pale stools, and 'tingling' sensations in her fingers. There are intermittent episodes of mild 'tummy pain' but she is particularly aware that she no longer fits into dresses she wore 18 months ago. She has noticed a few mouth ulcers during this time but is not particularly distressed by them. She denies fevers or bloody stools. She has a family history of Crohns disease, with her mother diagnosed with the condition in her 30s. A friend encouraged her to abstain from wheats, ryes and oats, which she remembers to have helped. Over the past 6 months, she reports significant stresses on her university masters course and personal problems with her boyfriend. Her only travel history is a recent trip to India 3 months ago.

She had recently seen her GP for these symptoms: her anti-endomysial antibody however, was negative on serological testing and an initial colonoscopy was non-diagnostic due to poor bowel preparation. Unfortunately, her sample for serum tissue transglutaminase antibody was lost. On examination, her abdomen is soft and non-tender, she appears pale and BMI = 14.7. She awaits a second colonoscopy. What is the most likely diagnosis?

	Crohns disease
	Irritable bowel syndrome
	Coeliac disease
	Ulcerative colitis
	Tropical sprue

□ Question 44 of 204

A 36-year-old man was diagnosed with ulcerative colitis 10 years previously. At his initial presentation a course of intravenous hydrocortisone was required to achieve remission. Subsequently, the patient's disease has been fairly well controlled with azathioprine, although occasional courses of oral steroids had been required to treat minor flares. The patient had experienced no extra-gastrointestinal manifestations of his disease and had no other past-medical history. Family history included the patient's father being diagnosed with sigmoid adenocarcinoma at the age of 67 years.

The patient was referred for routine screening colonoscopy. This demonstrated extensive colitis extending to the hepatic flexure but no active endoscopic inflammation or post-inflammatory polyps. Mapping biopsies were taken with no evidence of histological inflammation.

Prior to the procedure the patient stated his concern regarding his future risk of colorectal cancer due to his ulcerative colitis and expressed his willingness to undergo surveillance colonoscopy at the recommended time interval.

In what time interval should the patient undergo his next surveillance colonoscopy?

<input type="radio"/>	1 year
<input type="radio"/>	2 years
<input type="radio"/>	3 years
<input type="radio"/>	5 years

□ Question 46 of 204

A 60-year-old lady on the gastroenterology ward develops an acute episode of haematemesis in the night, the nurse who witnessed the event described the bleed as about one cupful of bright red blood. The patient has a known history of alcohol abuse, drinking 2 bottles of wine a day, and has a past medical history of ascites secondary to alcoholic liver cirrhosis, hypertension and type two diabetes mellitus. She was admitted initially for an ascitic drain earlier in the afternoon which has not occurred due to staff shortages in the medical team.

On examination she was afebrile, her heart rate was 110bpm, blood pressure was 104/81mmHg, respiratory rate of 20 breaths per minute and had an oxygen saturation of 97% on air. Cardiovascular and respiratory examination was unremarkable. Abdominal examination revealed a tensely distended abdomen with shifting dullness present. There are marked distended superficial veins on her abdominal surface. There was mild epigastric tenderness, and on rectal examination, there was a small amount of tarry black stool. She was not actively vomiting during the examination.

Intravenous fluid resuscitation was already started by the house officer on call, and blood samples including a cross-match were sent. The gastroenterology registrar on call has been informed and was arranging an emergency endoscopy for the patient.

Her previous blood results and a current venous blood gas (VBG) results are shown:

Blood results (earlier in the afternoon)

Na ⁺	134 mmol/l
K ⁺	4.8 mmol/l
Urea	10.9 mmol/l
Creatinine	100 µmol/l
Serum bilirubin	30 µmol/l
Serum alkaline phosphatase	165 IU/l
Serum aspartate aminotransferase	68 IU/l
C Reactive protein	6 mg/l
Haemoglobin	126 g/l

White cell count	7.6 x 10 ⁹ /L
Platelets	122 x 10 ⁹ /L
INR	1.8

VBG (Current)

pH	7.368
Lac	1.8 mmol/l
Base Excess	-2.4 mmol/l
Bicarbonate	26.9 mmol/l
Hb	11.0 g/dL

What is the next most appropriate immediate course of action to take?

<input type="checkbox"/>	Begin transfusion of O-negative blood
<input type="checkbox"/>	Intravenous proton pump inhibitor (PPI) bolus
<input type="checkbox"/>	Intravenous terlipressin bolus
<input type="checkbox"/>	Platelet transfusion

□ Question 47 of 204

A 45 year old female ITU nurse presents to the outpatient Gastroenterology clinic with a 12 week history of watery diarrhoea. She has been moving her bowels up to 9 times a day, the diarrhoea is painless and there is no blood in the stool. She said that she has also lost weight. As a nurse, she says that she regularly weighs herself and her BMI has dropped from 20 kg/m² to 18 kg/m² in the past 2 months. There is no vomiting but there is some nausea.

She also tells you that she has had two close family bereavements recently and that she is fearful of losing her job which is causing her a significant amount of stress and anxiety. As a teenager, she tells you that she had an eating disorder which required talking therapy for a period of time but that she has had no relapse for 20 years. She has a history of hypothyroidism for which she takes Levothyroxine 100mcg PO OD. She is otherwise well. She has a family history of hypothyroidism and type 1 diabetes.

Full physical examination including PR is unremarkable. Bloods show the following:

Hb	11.3 g/dl
MCV	92 fl
Platelets	421 * 10 ⁹ /l
WBC	11.4 * 10 ⁹ /l
Neuts	7.0 * 10 ⁹ /l

Na ⁺	142 mmol/l
K ⁺	3.8 mmol/l
Urea	4.8 mmol/l
Creatinine	56 µmol/l
CRP	16 mg/l
TSH	1.67 u/l

Bilirubin	6 µmol/l
-----------	----------

ALP	90 u/l
ALT	12 u/l
Albumin	45 g/l

Abdominal x-ray: no abnormality detected

Colonoscopy: normal mucosa to terminal ileum on visual inspection.

Considering your differential diagnosis, which two investigations would be most appropriate to perform in order to be most confident about making a diagnosis?

	OGD and free T4
	OGD and serum thyroglobulin
	Urine laxative screen and serum thyroglobulin
	OGD and histology of bowel biopsies
	Urine laxative screen and histology of large bowel biopsies

Question 48 of 204

A young man known to the gastroenterology team with alcoholic cirrhosis and grade two varices on his last OGD 7 months ago is admitted as a medical emergency to the resuscitation part of Accident and Emergency with haematemesis and melaena. It started 45 minutes ago when he immediately called an ambulance. He is able to tell you that apart from the cirrhosis and varices he does not have any other problems, and he takes only thiamine, vitamin B co-strong and propranolol (but he is unsure of the dose). He says he has been well over the past week, with no symptoms of disease, and your screening questions reveal nothing important. He admits that he still occasionally drinks alcohol, but hasn't in the past 2 weeks, and that he used to have an opiate based drug addiction, for which he's been clean the past 3 years.

His initial observations are as follows:

Respiratory rate	22 breaths/minute
Heart rate	102 beats/minute
Temperature	36.2°C
Blood pressure	85/33 mmHg
Saturations	100% on 4L nasal

Initial bloods

Hb	90 g/l
Platelets	72 * 10 ⁹ /l
WBC	6.4 * 10 ⁹ /l

His ECG shows RBBB and T wave inversion in leads V1 and V2 only.

After 3L of fluid resuscitation:

Hb	78 g/l
Platelets	63 * 10 ⁹ /l

WBC	5.9 * 10 ⁹ /l
-----	--------------------------

Na ⁺	129 mmol/l
K ⁺	4.2 mmol/l
Urea	14.2 mmol/l
Creatinine	75 µmol/l

Bilirubin	43 µmol/l
ALP	152 u/l
ALT	41 u/l
Albumin	29 g/l

PT	20.4 s
INR	1.7
APTT	38 s
Fibrinogen	0.8 g/L

His repeat observations are as follows:

Respiratory rate	18 breaths/minute
Heart rate	92 beats/minute
Temperature	36.4°C
Blood pressure	105/65 mmHg
Saturations	99% on 2L nasal

What medication would you give him?

	Fresh frozen plasma, Terlipressin, Ceftriaxone
	Fresh frozen plasma, Terlipressin, Ceftriaxone, Platelets, Packed red cells
	Fresh frozen plasma, Ceftriaxone, Platelets
	Fresh frozen plasma, Terlipressin, Ceftriaxone, Packed red cells
	Fresh frozen plasma, Terlipressin, Packed red cells, Platelets

□ Question 50 of 204

□ □

You are working on the gastroenterology ward in your local district general hospital, doing a ward round, when you come to examine one of your well known NASH (non-alcoholic steatohepatitis) cirrhosis patients. He's a 43-year-old man who had been admitted to the ward 3 days ago with a lower respiratory tract infection which has responded well to antibiotics. The patient appears clinically well from the end of the bed and has no complaints. He says that his ascites has been reasonably well managed over the past 4 years since diagnosis, needing only one ascitic drain during the admission that led to the diagnosis. On examination his chest appears to be clear today, his abdomen is soft and non-tender, and you can elicit a small amount of ascites on examination.

His blood results from this morning are as follows:

Hb	118 g/l
Platelets	$102 \times 10^9/l$
WBC	$4.5 \times 10^9/l$

Na ⁺	128 mmol/l
K ⁺	4.2 mmol/l
Urea	1.4 mmol/l
Creatinine	45 μ mol/l

Bilirubin	20 μ mol/l
ALP	134 u/l
ALT	24 u/l
Albumin	30 g/l

He tells you that his sodium has always given him a bit of trouble, and looking back at old results you noted that his usual sodium in clinic is consistently 133. His only medication is spironolactone 100mg twice daily

How should you manage this patient's hyponatraemia?

	Carry on spironolactone and fluid restrict to 1L/day
	Stop spironolactone and fluid restrict to 1L/day
	Reduce spironolactone to 50mg twice daily and monitor
	No change to medications - just monitor
	Stop spironolactone and monitor

□ Question 50 of 204

□ □

You are working on the gastroenterology ward in your local district general hospital, doing a ward round, when you come to examine one of your well known NASH (non-alcoholic steatohepatitis) cirrhosis patients. He's a 43-year-old man who had been admitted to the ward 3 days ago with a lower respiratory tract infection which has responded well to antibiotics. The patient appears clinically well from the end of the bed and has no complaints. He says that his ascites has been reasonably well managed over the past 4 years since diagnosis, needing only one ascitic drain during the admission that led to the diagnosis. On examination his chest appears to be clear today, his abdomen is soft and non-tender, and you can elicit a small amount of ascites on examination.

His blood results from this morning are as follows:

Hb	118 g/l
Platelets	$102 \times 10^9/l$
WBC	$4.5 \times 10^9/l$

Na ⁺	128 mmol/l
K ⁺	4.2 mmol/l
Urea	1.4 mmol/l
Creatinine	45 μ mol/l

Bilirubin	20 μ mol/l
ALP	134 u/l
ALT	24 u/l
Albumin	30 g/l

He tells you that his sodium has always given him a bit of trouble, and looking back at old results you noted that his usual sodium in clinic is consistently 133. His only medication is spironolactone 100mg twice daily

How should you manage this patient's hyponatraemia?

□ Question 51 of 204

□ □

A 40-year-old woman with a background of Sjogren's syndrome presents with fatigue and itchy skin. She has not been commenced on any new medications or travelled recently. On examination, she is found to have a palpable liver edge. Further investigations reveal the following results:

Bilirubin	22 $\mu\text{mol/l}$
ALP	400 u/l
ALT	35 u/l

Anti-mitochondrial antibodies positive, anti-smooth muscle antibodies negative

Anti-HBs positive, HBsAg negative, HBcAg negative

Hepatitis C negative

What is the most likely diagnosis?

	Primary biliary cirrhosis
	Primary sclerosing cholangitis
	Autoimmune hepatitis
	Acute Hepatitis B infection
	Hepatitis B carrier

□ Question 52 of 204

A 60-year-old man is admitted with severe upper abdominal pain, nausea and dizziness lasting for the last day. On further questioning he admits to experiencing intermittent mild upper abdominal pain for the last month, typically after meals. His past medical history includes hypertension, type 2 diabetes, osteoarthritis and myocardial infarction 5 years ago for which he had a stent placed. His current medications include aspirin, ramipril, amlodipine, metformin, naproxen and paracetamol.

Whilst in the department he develops diarrhoea and examination of the stool shows melaena.

His blood pressure is 110/55 mmHg and heart rate is 95 beats per minute. On examination, he is tender in the epigastrium with no peritonism and normal bowel sounds. Examination of other systems is normal.

Blood results:

Hb	95 g/l	Na ⁺	145 mmol/l
Platelets	200 * 10 ⁹ /l	K ⁺	4.5 mmol/l
WBC	8 * 10 ⁹ /l	Urea	12 mmol/l
Neuts	3 * 10 ⁹ /l	Creatinine	102 µmol/l

He is treated given intravenous fluids and analgesia. All his regular analgesia aside from paracetamol is withheld. and taken to endoscopy later that day. A 1cm ulcer is seen in the gastric antrum with an adherent clot. This is clipped and injected with adrenalin. He recovers well from sedation and on return to the ward his blood pressure is 135/70 mmHg and heart rate 80 beats per minute. He has no further diarrhoea or vomiting and repeat haemoglobin is 121 g/l.

On discharge, what advice should he be given regarding his non-steroidal anti-inflammatory drugs?

	Continue both aspirin and naproxen and add a proton pump inhibitor
	Stop naproxen and aspirin. Start a proton pump inhibitor.
	Stop naproxen, change aspirin to clopidogrel and add a proton pump inhibitor

	Stop naproxen, change aspirin to dalteparin and add a proton pump inhibitor
	Stop naproxen, continue aspirin and add a proton pump inhibitor

□ Question 55 of 204

□ □

A 49 year-old woman is referred by her GP with a worsening 3-week history of chest pain and burning behind the sternum after eating. Other symptoms include tiredness and the patient has noticed that over the past four months her clothes have started to become much looser on her, although she has put this down to stress at work and skipping meals. She denies night sweats and her only past medical history is mild hypertension for which she takes ramipril. She is on no other regular medication and her father died of lung cancer at the age of 67. Her mother is still alive and well. She drinks 10-15 units per week and has a 25 pack year history.

On examination, heart sounds 1 and 2 are present with no added sounds, her pulse is regular and the character is good and she has clear lung fields. Abdominal exam reveals a soft, non-tender abdomen and bowel sounds are present.

She is referred to gastroenterology where an endoscopy reveals a 2cm diameter area that looks roughened and suspicious. Biopsy of this area is reported as having large number of lymphocytes that have irregular nuclear contours with abundant cytoplasm.

Which of the following is the most appropriate first-line treatment for this condition.

	Endoscopic surgical excision
	Chemotherapy
	Open surgery
	Amoxicillin, clarithromycin and omeprazole treatment
	Radiotherapy

Question 56 of 204

□ □

A 24 year-old man presents to his GP because he is worried that he may have bowel cancer. He does not currently have any clinical features that would suggest bowel cancer and is taking no medication. His father died of colon cancer at the age of 49 and his paternal uncle also had bowel cancer diagnosed at the age of 44. He was previously referred for a colonoscopy four months ago which was normal.

His abdominal examination is normal. You rearrange for the patient to have a colonoscopy in 2 years time.

What is the most appropriate next management step?

	Check for a mutation in chromosome 5q21
	Check for a DNA mismatch repair gene mutation
	Perform a computed tomography (CT) with contrast scan of his abdomen
	Check carcinoembryonic antigen (CEA) level
	Check for a P53 mutation

Dashboard

□ Question 57 of 204

A 45-year-old man with long-standing Crohns disease is reviewed in gastroenterology clinic. Initial diagnosis was 12 years previously when he presented as an emergency due to a perianal fistula and associated abscess. This had necessitated emergency surgery and treatment with intravenous corticosteroids. Once remission had been obtained through use of corticosteroids, azathioprine had been used as an immunomodulating agent to maintain remission. Subsequently, the patients disease had been fairly well controlled with disease flares on average less than every 2 years. When flares occurred they tended to cause the patient severe bouts of bloody diarrhoea. Large bowel endoscopies performed following disease exacerbation tended to show colonic inflammation with multiple biopsies consistent with the original histological diagnosis of Crohns disease.

Two months previously, the patients routine monitoring bloods had demonstrated derangement of liver function tests prompting further investigations (details given below). Following conclusion of these investigations, the patient had been initiated on cholestyramine and vitamin supplementation.

Alanine aminotransferase	45 U / L
Alkaline phosphatase	356 U / L
Bilirubin	105 micromol / L
Albumin	30 g / L
ANCA (PR3)	Negative
ANCA (MPO)	Positive
Anti-smooth muscle antibody	Positive

Endoscopic retrograde cholangio-pancreatogram: multiple intrahepatic bile duct strictures and beading

Following discussion with the patient about his new diagnosis he raised his concerns about his future risk of bowel cancer and whether he would require regular endoscopic surveillance.

What is the appropriate frequency of surveillance colonoscopy for this patient?

Not indicated

	Every 1 year
	Every 3 years
	Every 5 years
	Every 10 years

□ Question 58 of 204

A 25-year-old woman is reviewed in gastroenterology clinic six weeks after a recent hospital admission with abdominal symptoms. During the initial admission, the patient had presented with a 6 week history of very frequent bloody diarrhoea, a 10 kg weight loss and intermittent severe abdominal pain. Endoscopy had demonstrated a pan-colitis with histological features consistent with Crohn's disease. In addition, a CT scan of the abdomen had revealed a localised abscess associated with the proximal colon that had required percutaneous drainage and a course of IV antibiotics.

In addition to the above, the patient had been treated with IV hydrocortisone followed by a reducing course of prednisolone (initially 40 mg daily, tapered over 8 weeks). Steroid treatment had initially given a good response with the patients symptoms markedly improving during her hospital stay. Azathioprine treatment had been initiated prior to discharge in an attempt to maintain remission during wean of oral steroids.

In clinic, the patient reported being concordant with azathioprine therapy. However, she found that when she had reduced her prednisolone dose below 15 mg daily, she had recurrent abdominal pains and frequent bloody diarrhoea (although less severe than at presentation). She had also noted some pain to the left side of her anus when defecating.

Examination of the patients abdomen revealed some lower abdominal tenderness but without features of peritonitis. External examination showed an area of ulceration one centimetre lateral to the anus.

Haemoglobin	95 g / dL
Mean cell volume	98 fL
White cell count	16.9×10^9 / microlitre
Neutrophils	12.6×10^9 / microlitre
Platelets	451×10^9 / microlitre
Urea	8.0 mmol / L
Creatinine	97 micromol / L
Sodium	143 mmol / L
Potassium	3.9 mmol / L
CRP	125 mg / L

What is the appropriate next line treatment to induce remission in this patient?

	Colectomy
	Methotrexate
	Metronidazole
	Infliximab
	Budesonide

□ Question 59 of 204

A 42-year-old woman attends the gastroenterology clinic for outpatient review approximately one month following a recent admission to hospital. She had presented with a 6 week history of frequent bloody diarrhoea and cramping abdominal pain. In addition, she reported a long-standing tendency to suffer from multiple mouth ulcers. She had lost approximately, 8 kilograms of weight between the onset of diarrhoea and presentation to hospital.

The results of investigations performed during the hospital admission are given below. Following investigation, a short course of intravenous steroids had been given followed by oral prednisolone (initial dose 40 mg daily, slowly tapered over 8 weeks).

The patient reported near complete resolution of her previous symptoms and welcome relief from her oral ulceration. She had regained some of the weight she had previously lost and reported her appetite to be good. A discussion was had with the patient about future therapy and she indicated that she would prefer to consider the initiation of further medication to attempt to maintain her symptom remission.

Stool microscopy: no organisms seen

Stool culture: no organisms grown

Colonoscopy: patchy inflammation with 'cobblestone' appearance affecting ascending and transverse colon and terminal ileum

Colonic histology: multiple samples demonstrating signs of chronic transmural inflammation, crypt abscesses and submucosal fibrosis

CT abdomen: no evidence of intra-abdominal collection, structuring or abnormal fistulation

What is the most appropriate medication to maintain disease remission in this patient?

	Methotrexate
	Infliximab
	Budesonide

	Azathioprine
	Metronidazole

A 74-year-old lady presents with non-bloody diarrhoea for five days. She was treated for *Clostridium difficile* infection two weeks ago. In the last five days, she has experienced six episodes of diarrhoea per day. Her past medical history includes heart failure, lymphoma and type two diabetes mellitus. On examination, her blood pressure is 134/88 mmHg, pulse is 90/min, temperature is 38°C, respiratory rate is 16/min and oxygen saturation is 97% on air. She is slightly tender in the left lower quadrant. There are no signs of peritonism and bowel sound is normal. Stool culture result shows positive for glutamate dehydrogenase and toxin enzyme immunoassay. Which of the following drug should be used?

	Oral metronidazole
	Intravenous vancomycin
	Intravenous metronidazole
	Oral fidaxomicin
	Intravenous fluid and paracetamol

□ Question 62 of 204

□ □

A 24 year old Greek man presented after his partner reported a personality change over the past three weeks. She reported that he had been very low in mood, and had been behaving strangely. He reported being a little fatigued over the past couple of weeks. Neurological examination was unremarkable other than a rest tremor in his right hand. There was evidence of scleral icterus, and the liver edge was just palpable below the costal margin.

Initial blood results are shown below:

Haemoglobin	98 g/L
Platelets	$156 \times 10^9/L$
Mean corpuscular volume	89 fl
White cell count	$6.8 \times 10^9/L$
Reticulocyte count	5%
Alkaline phosphatase	142 U/L
Bilirubin	55 mol/L
Alanine transaminase	105 U/L
Albumin	35 g/L

Which investigation is most likely to reveal the underlying cause of his anaemia?

	Direct antiglobulin test
	24-hour urinary copper excretion
	Vitamin B12 level
	Iron profile

Question 64 of 204

□ □

A 45-year-old man with a 20-year history of ulcerative colitis was reviewed in the inflammatory bowel disease clinic. He opens his bowels once a day with no rectal bleeding. Aside from some fatigue, he is asymptomatic. He had required multiple courses of steroids over the past 4 years due to recurrent flare-ups of his colitis. He had gone into remission a year ago after receiving a course of infliximab. He had a colonoscopy 18 months ago which showed extensive left sided disease with friable mucosa and easy bleeding on contact with the endoscope. A repeat colonoscopy 6 months ago showed improved appearances and evidence of mucosal healing.

Blood tests done in clinic show:

Hb	102 g/l	Na ⁺	139 mmol/l	Bilirubin	63 µmol/l
Platelets	275 * 10 ⁹ /l	K ⁺	4.2 mmol/l	ALP	350 u/l
WBC	7.5 * 10 ⁹ /l	Urea	3.2 mmol/l	ALT	55 u/l
Neuts	4.2 * 10 ⁹ /l	Creatinine	90 µmol/l	γGT	136 u/l
Lymphs	1.2 * 10 ⁹ /l			Albumin	33 g/l
INR	1.3				

Which is the most appropriate investigation to confirm the cause of this patient's abnormal LFTs?

	Ultrasound liver
	CT abdomen
	Endoscopic retrograde cholangiopancreatography
	Magnetic resonance cholangiopancreatography
	Liver biopsy

Question 65 of 204

□ □

A 48-year-old known alcoholic liver disease patient is admitted via Accident and Emergency with profuse haematemesis. He has been drinking 6 litres of cider per day for the last week. He denies abdominal pain or melena. On examination, he has peripheral stigmata of chronic liver disease and is very pale. His abdomen is soft and he has no tenderness or hepatosplenomegaly. His blood pressure is 90/56 mmHg and he is tachycardic at 120/min. His last OGD 6 months ago showed 3 columns of small varices.

His blood results are as follows:

Hb	58 g/l
Platelets	$109 \times 10^9/l$
WBC	$8.4 \times 10^9/l$
INR	1.6
PT	19 seconds

Na ⁺	144 mmol/l
K ⁺	4.9 mmol/l
Urea	18.1 mmol/l
Creatinine	97 μ mol/l
CRP	5 mg/l

Bilirubin	87 μ mol/l
ALP	189 u/l
ALT	71 u/l
Albumin	28 g/l

He is transfused 2 units by A&E and given 2 units of Fresh Frozen plasma to correct his coagulopathy. He is also given Tazocin 4.5g TDS and Terlipressin 1mg QDS after discussion with the on call Gastroenterologist. He is taken for OGD which shows bleeding oesophageal varices. He has 5 bands applied to the varices but the endoscopist is unable to stop the bleeding. He is returned to the ward where he continues to have haematemesis with low blood pressure and ongoing tachycardia.

What is the next step in his management?

	Repeat OGD
	TIPSS
	Sengstaken Blakemore tube
	Increase Terlipressin to 2mg
	Further FFP

□ Question 67 of 204

□ □

A 40-year-old man who recently had an appendicectomy presents to hospital unwell. He has generalised abdominal pain and pyrexia. Initial bloods are presented below.

Hb	134 g/l	Na ⁺	139 mmol/l	Bilirubin	18 µmol/l	B12	900ng/l
Platelets	490 * 10 ⁹ /l	K ⁺	4.1 mmol/l	ALP	120 u/l	Folate	2.1µg/l
WBC	23.2 * 10 ⁹ /l	Urea	7.6 mmol/l	ALT	35 u/l	Iron	18µmol/l
Neuts	19.8 * 10 ⁹ /l	Creatinine	101 µmol/l	γGT	30 u/l		
Lymphs	3.2 * 10 ⁹ /l			Albumin	41 g/l		
Eosin	0.1 * 10 ⁹ /l						

Automated lab haematinics show a grossly elevated serum B12 with normal folate and iron. Blood culture confirms gram-negative septicaemia. What is the likely diagnosis?

	Atypical respiratory tract infection
	Infectious mononucleosis
	Liver abscess
	Catheter associated urinary tract infection
	Infective endocarditis

□ Question 68 of 204

A 25-year-old female undergraduate student presented to the gastroenterology outpatient clinic after referral from her GP. The referral letter stated that the patient had a three-year history of irritable bowel syndrome (IBS) and was complaining mainly of constipation. The GP had tried dietary advice and different laxatives, including senna and sodium docusate in full doses and a trial of macrogol with no benefit. The patient stated that the problem was mainly happening during exams. She underwent appendectomy 5 years ago with no postoperative complications. Blood investigations were as follows:

Hb	120 g/l
Platelets	$310 \times 10^9/l$
WBC	$8 \times 10^9/l$

Na ⁺	140 mmol/l
K ⁺	4.4 mmol/l
Urea	6.5 mmol/l
Creatinine	100 μ mol/l

What is the next step in management?

	Add tricyclic anti-depressant (TCA)
	Add selective serotonin re-uptake inhibitor (SSRI)
	Increase the dose current laxatives and advice to relax
	Add lactulose
	Add linaclotide

Overall score: **0%**

Question 69 of 204

A 54 year old Caucasian female presents with a 3 month history of dysphagia to bread and solid meats, with no problems with swallowing oral liquids. She has lost about 2 stones in weight unintentionally during this period. She denies any night sweats or fevers, haematemesis, change in bowel habit or malaena. She reports no change in her voice or aspiration episodes. On examination, you note koilonychias and an enlarged tongue on examination with conjunctival pallor. Her blood tests are as follows:

Hb	7.6 g/dl
MCV	62 fl
Platelets	246 * 10 ⁹ /l
WBC	7.2 * 10 ⁹ /l
Ferritin	22 ng/ml
Na ⁺	142 mmol/l
K ⁺	4.2 mmol/l
Urea	5.6 mmol/l
Creatinine	55 µmol/l
CRP	20 mg/l

Her GP refers her for an urgent upper oesophageal-gastric endoscopy (OGD) as part of the 2 week wait of suspected cancer. OGD reveals narrowed distal oesophageal lumen caused by webs that are ruptured as the scope is passed. What is the likely diagnosis?

	Plummer-Vinson syndrome
	Oesophageal squamous cell carcinoma
	Oesophageal adenocarcinoma

	Pharyngeal carcinoma
	Oesophageal rings

Dashboard

Overall score: **0%**

□ Question 74 of 204

A 38-year-old man is referred in by his GP with increasing frequency of diarrhoea over the last 4 days. He is a known ulcerative colitis patient who is well managed on azathioprine 200mg OD and mesalazine 2.4mg BD. He last had a flare 2 years ago and has been well in the interim. He is passing up to 10 watery motions a day and is suffering from faecal urgency and nocturnal episodes. He describes cramping left iliac fossa pain. There is no blood or mucus in the stools. On examination, he is febrile at 38.2 degrees celsius. His blood pressure is 120/75 mmHg and his heart rate is 100/min. On examination, he is underweight with a BMI of 18.5 and dehydrated. His abdomen is soft but he is tender in the left iliac fossa. He refuses a PR examination. Respiratory and cardiovascular examinations are normal.

His blood tests show:

Hb	110 g/l
Platelets	$189 \times 10^9/l$
WBC	$3.8 \times 10^9/l$
Neutrophils	$0.89 \times 10^9/l$
INR	1.1 (0.9-1.2)

Na ⁺	136 mmol/l
K ⁺	4.9 mmol/l
Urea	8.0 mmol/l
Creatinine	100 μ mol/l
Magnesium	0.79 mmol/L (0.7-1.0)
Calcium	2.4 mmol/L (2.1-2.58)
CRP	78 mg/l

Bilirubin	5 μ mol/l

ALP	78 u/l
ALT	28 u/l
Albumin	33 g/l

He is started on IV hydrocortisone 100mg QDS and IV fluids. Stool specimens are sent and are reported as negative for *C. difficile* toxin. He has a flexible sigmoidoscopy the next day which shows widespread left sided colitis. The biopsy results show the presence of inclusion bodies in the colonic mucosa. What is the appropriate treatment to start for this gentleman?

	Infliximab
	Ganciclovir
	Metronidazole
	Fluconazole
	Tazocin

□ Question 76 of 204

A 36-year-old man attends gastroenterology clinic with an 8-month history of watery diarrhoea. He opens his bowels up to 15 times a day and this is not associated with any rectal bleeding. His symptoms are not relieved by loperamide. He has a history of Crohn's disease which was diagnosed 5 years ago and had an ileal resection 12 months ago following an inflammatory stricture. He does not smoke and drinks approximately 35 units of alcohol a week. His medications include omeprazole 20mg OD, paracetamol 1g QDS and ibuprofen 400mg TDS PRN.

His blood tests are:

Hb	115 g/l	Na ⁺	139 mmol/l	Bilirubin	12 µmol/l
Platelets	395 * 10 ⁹ /l	K ⁺	3.9 mmol/l	ALP	100 u/l
WBC	10.5 * 10 ⁹ /l	Urea	6.5 mmol/l	ALT	42 u/l
Neuts	5.5 * 10 ⁹ /l	Creatinine	100 µmol/l	γGT	65 u/l
CRP	4 mg/L			Albumin	37 g/l
Amylase	124 U/L				

Which investigation is most likely to confirm the diagnosis?

□ Question 77 of 204

A 50-year-old man with known alcoholic hepatitis is admitted to the Emergency Department generally unwell. He has had vague abdominal pain and general malaise for 4 days. His wife tells you he has been eating and drinking much less in that time and confirms he has been abstinent from alcohol for over a year.

On examination he appears clinically dehydrated and is drowsy. His heart rate is 121 beats per minute and his blood pressure is 102/55 mmHg. His temperature is 37.4 °C. His chest is clear. His abdomen is soft with suprapubic tenderness but no organomegaly. There is some dullness in the flanks.

His urine dip is positive for nitrites and 1+ leucocytes.

His blood tests are as follows:

Hb	115 g/l	Na ⁺	125 mmol/l	Bilirubin	24 µmol/l
Platelets	189 * 10 ⁹ /l	K ⁺	4.9 mmol/l	ALP	250 u/l
WBC	14 * 10 ⁹ /l	Urea	11 mmol/l	ALT	124 u/l
Neuts	10 * 10 ⁹ /l	Creatinine	230 µmol/l	γGT	255 u/l
Lymphs	2.5 * 10 ⁹ /l	CRP	75 mg/dl	Albumin	30 g/l

He is treated with antibiotics and normal saline but after 24 hours his sodium is 124 mmol/l and creatinine is 229 µmol/l.

His urine sodium is 12 mmol/l and an ultrasound of the abdomen shows mild ascites, a cirrhotic liver and a normal renal tract.

What is the next most appropriate step?

	5% dextrose
	Fluid restriction
	Hartmann's solution

	Human albumin solution
	Hypertonic saline

□ Question 78 of 204

□ □

A 60-year-old man presented to the Emergency Department with profuse, foul smelling diarrhoea, abdominal pain and fever.

His past medical history included hypertension, gout and osteoarthritis. His bowel habits are usually regular and there has been no recent change. Two weeks ago he underwent an endoscopy for dyspepsia and was diagnosed with gastritis. He was currently taking amlodipine 5mg, omeprazole 20mg, simvastatin 20mg, salbutamol inhaler one puff as required. He had no known drug allergies. He recently returned from a business trip to Paris.

On examination he was unwell with a heart rate of 110 beats/min and regular, a blood pressure of 100/60 mmHg, oxygen saturations of 96% on air and a temperature of 38°C. He was peripherally shut down with a capillary refill time of 3 seconds. Abdominal examination revealed a distended and diffusely tender abdomen with guarding.

Initial bloods showed:

Na+	140 mmol/L
K+	5.0 mmol/L
Urea	10 mmol/L
Creatinine	130 mmol/L
Hb	13.0 g/dL
WBC	$20.0 \times 10^9/L$
Neutrophils	89%
LFTs	Normal

Abdominal X-ray showed a loss of bowel wall architecture and thumb-printing consistent. Erect chest x-ray showed clear lung fields with no air under the diaphragm.

What is the most likely cause of his symptoms?

--	--

	Salmonellosis
	Inflammatory bowel disease
	Ischaemic colitis
	Diverticulitis
	Omeprazole-induced <i>Clostridium difficile</i> infection

☐ Question 84 of 204

A 75-year-old man is reviewed in gastroenterology clinic as part of on-going follow-up for Barrett's oesophagus. The patient had been referred by his GP 2 months previously due to long-standing symptoms of gastro-oesophageal reflux: specifically, heartburn following eating and acid reflux upon lying flat in bed. No red-flag features of upper gastrointestinal tract malignancy had been identified.

An initial endoscopy was performed with results as documented below. Following discussion of the histology results, the patient elected to undergo endoscopic radiofrequency ablation. The procedure was uncomplicated aside from some mild chest pain in the first few days of recovery.

The patient was otherwise in good health, with other past medical history including only hypertension and osteoarthritis of both knees. Regular medications included paracetamol, omeprazole, ramipril and bendroflumethiazide. The patient reported a previous adverse reaction to penicillin but could not recall the details of this event.

There was no family history of Barrett's oesophagus or oesophageal adenocarcinoma. The patient had never smoked and reported consuming 20 units of alcohol per week.

Report from initial endoscopy: minor hiatus hernia; 5 cm length of circumferential salmon-coloured epithelium extending above gastro-oesophageal junction; mild oesophagitis elsewhere; no mass lesion or ulceration in oesophagus or stomach; quadrant biopsies taken as per protocol.

Histology from endoscopic biopsies: all samples demonstrate flat intestinal metaplasia; mild dysplasia present in 4 of 8 samples; no high-grade dysplasia or adenocarcinoma.

Following successful endoscopic therapy, what is the appropriate schedule for follow-up surveillance endoscopy?

	Every 6 months for 2 years, then every 1 year thereafter
	Every 3 months for 1 year, then every 6 months for 1 year, then every 1 year thereafter
	Every 1 year
	Every 6 months for 1 year, then every 1 year thereafter

Every 3 years

□ Question 84 of 204

A 75-year-old man is reviewed in gastroenterology clinic as part of on-going follow-up for Barrett's oesophagus. The patient had been referred by his GP 2 months previously due to long-standing symptoms of gastro-oesophageal reflux: specifically, heartburn following eating and acid reflux upon lying flat in bed. No red-flag features of upper gastrointestinal tract malignancy had been identified.

An initial endoscopy was performed with results as documented below. Following discussion of the histology results, the patient elected to undergo endoscopic radiofrequency ablation. The procedure was uncomplicated aside from some mild chest pain in the first few days of recovery.

The patient was otherwise in good health, with other past medical history including only hypertension and osteoarthritis of both knees. Regular medications included paracetamol, omeprazole, ramipril and bendroflumethiazide. The patient reported a previous adverse reaction to penicillin but could not recall the details of this event.

There was no family history of Barrett's oesophagus or oesophageal adenocarcinoma. The patient had never smoked and reported consuming 20 units of alcohol per week.

Report from initial endoscopy: minor hiatus hernia; 5 cm length of circumferential salmon-coloured epithelium extending above gastro-oesophageal junction; mild oesophagitis elsewhere; no mass lesion or ulceration in oesophagus or stomach; quadrant biopsies taken as per protocol.

Histology from endoscopic biopsies: all samples demonstrate flat intestinal metaplasia; mild dysplasia present in 4 of 8 samples; no high-grade dysplasia or adenocarcinoma.

Following successful endoscopic therapy, what is the appropriate schedule for follow-up surveillance endoscopy?

	Every 6 months for 2 years, then every 1 year thereafter
	Every 3 months for 1 year, then every 6 months for 1 year, then every 1 year thereafter
	Every 1 year
	Every 6 months for 1 year, then every 1 year thereafter

Every 3 years

Question 85 of 204

□ □

A 30-year-old woman presents with intermittent episodes of mild jaundice. She states that she is otherwise well during these episodes but has noted that they tend to coincide with her period or occur when she has an upper respiratory tract infection. She states she thinks her mother has had similar episodes. Her blood test results are as follows.

Hb	120 g/l
Platelets	$220 \times 10^9/l$
WBC	$5.2 \times 10^9/l$

Urea	4.3 mmol/l
Creatinine	80 μ mol/l

Bilirubin	40 μ mol/l
ALP	50 u/l
ALT	35 u/l
γ GT	20 u/l
Albumin	40 g/l

What is the most likely diagnosis?

	Autoimmune hepatitis
	Hepatitis B
	Hepatitis C
	Gilberts syndrome

	Crigler-Najjar syndrome

Question 86 of 204

□ □

A 26-year-old woman presents to the Emergency department some 2 weeks after returning from her honeymoon in the Seychelles. Since returning she has suffered from intermittent abdominal bloating and diarrhoea and feels she has lost a little weight. Physical examination reveals a blood pressure of 118/82 mmHg, and her pulse is 70 and regular. There is mild abdominal distension and her body mass index is 22 kg/m²

Investigations:

Hb	110 g/l	Na ⁺	138 mmol/l
Platelets	210 * 10 ⁹ /l	K ⁺	4.0 mmol/l
WBC	11.2 * 10 ⁹ /l	Urea	6.9 mmol/l
Neuts	8.1 * 10 ⁹ /l	Creatinine	89 µmol/l
Lymphs	1.5 * 10 ⁹ /l	CRP	82 mg/l
Albumin	34 g/l		

Which of the following is the most appropriate intervention?

	Amoxicillin
	Ciprofloxacin
	Gluten free diet
	Lactose free diet
	Metronidazole

□ Question 87 of 204

A 60-year-old woman with a known history of alcohol dependency presents with a 4-hour history of haematemesis and abdominal discomfort. She has no history of upper GI bleed but does report several previous episodes of passing black stools. She has asthma and a family history of type II diabetes mellitus. A previous abdominal ultrasound has shown hepatic cirrhosis.

Today, she appears unwell. She continues to vomit small amounts of blood. On examination, her blood pressure is 120/85mmHg and pulse rate is 90 beats per minute. Her chest is clear and her abdomen is soft, though she has some epigastric tenderness. Rectal examination reveals melaena.

An intravenous cannula is inserted and blood is taken.

Blood tests show:

Hb	98 g/l
Platelets	$180 \times 10^9/l$
WBC	$6.3 \times 10^9/l$

Fibrinogen	2.3 g/L
APTT	30 seconds
PT	12.5 seconds

Na ⁺	142 mmol/l
K ⁺	4.9 mmol/l
Urea	10 mmol/l
Creatinine	100 μ mol/l

Fluids are started and arrangements are made to send the patient to the endoscopy suite.

What should be administered prior to endoscopy?

	Terlipressin
	Octreotide
	Platelets
	Packed red cells
	Fresh frozen plasma (FFP)

Question 88 of 204

A 62-year-old man who is an immigrant from Turkey is investigated for abnormal liver function tests. His most liver function tests show the following:

Bilirubin	42 $\mu\text{mol/l}$
ALP	221 u/l
ALT	98 u/l
γGT	131 u/l
Albumin	36 g/l

He does complain of an occasional dull ache in the right upper quadrant. A CT scan is requested:

Over the past two weeks he has also had recurrent episodes of an intensely itchy urticarial rash developing. These episodes typically last around 2 hours before settling and are helped by oral antihistamines.

What is the most likely diagnosis?

<input type="checkbox"/>	Budd-Chiari Syndrome
<input type="checkbox"/>	Amoebic liver abscess
<input type="checkbox"/>	Cysticercosis
<input type="checkbox"/>	Hepatocellular carcinoma
<input type="checkbox"/>	Hydatid cyst

□ Question 89 of 204

A 33-year-old lady was referred to the outpatient gastroenterology clinic by her GP who had diagnosed Irritable Bowel Syndrome refractory to symptomatic management. Her symptoms commenced six months ago with central abdominal cramping bloating made worse with eating wheat and oat based foods. She also noticed that the onset of the abdominal cramping was often associated with faecal urgency. Despite a prolonged trial of mebeverine, hyoscine butylbromide and peppermint oil there was no improvement in her symptoms. Her symptoms were however alleviated by avoiding the precipitating foods. She had not lost any weight and did not pass any blood per rectum; other than a family history of maternal depression there was no family history of note. Her past medical history was comprised depression for which she was prescribed citalopram 40mg OD; this was increased recently following worsening of her mood over the last few weeks.

Examination revealed the presence of a well 33-year-old lady. Her blood pressure was 112/72mmHg, heart rate 78 bpm and temperature 36.6°C. Examination of her cardiovascular and respiratory systems was unremarkable. Examination of her gastrointestinal system was similarly unremarkable with no organomegaly, normal bowel sounds and the absence of lymphadenopathy. Examination of her forearms revealed the presence of multiple superficial lacerations.

Investigations conducted by her GP are as shown:

Hb	105 g/l
MCV	81 fl
Platelets	224 * 10 ⁹ /l
WBC	8.2 * 10 ⁹ /l

Bilirubin	19 µmol/l
ALP	142 u/l
ALT	33 u/l
Protein	81 g/l
Albumin	39 g/l

ESR	9 mm/hr
CRP	12 mg/l
TSH	0.75 (NR 0.4-3.6mu/ml)
FT4	11.6 (NR 4.5-13.6 mcg/dl)
IgG	7.2 (NR 5.8-15.4g/l)
IgA	0.2 (NR 0.64-2.97g/l)
IgM	1.2 (0.75-2.20g/l)
B12	224 (NR 160-900 ng/l)
Anti-endomysial antibody	negative

What is the next most appropriate management option?

<input type="radio"/>	Organise oesophageal motility studies
<input type="radio"/>	Organise upper GI endoscopy and biopsy
<input type="radio"/>	Commence trial with low dose amitriptyline
<input type="radio"/>	Commence gluten exclusion diet
<input type="radio"/>	Commence trial with domperidone

□ Question 90 of 204

□ □

A 45 year old man admitted to the gastroenterology ward to detox from excessive alcohol consumption. He is known to have alcohol dependence syndrome but has no other past medical history and no known diagnosis of alcoholic cirrhosis. On examination he is noted to have a distended abdomen with evidence of shifting dullness and a succussion splash. He is taken down for an ultrasound of his abdomen and an appropriate site for an ascitic tap is marked in the left iliac fossa by the radiologist. Before doing the ascitic tap you check his bloods from today, they are as follows:

Hb	83 g/l
Platelets	$56 \times 10^9/l$
WBC	$3.5 \times 10^9/l$

Na ⁺	128 mmol/l
K ⁺	3.2 mmol/l
Urea	2.2 mmol/l
Creatinine	45 μ mol/l

Bilirubin	35 μ mol/l
ALP	145 u/l
ALT	24 u/l
Albumin	32 g/l

INR	1.8
APTT	55 s
Fibrinogen	1.3 g/L

Before doing an ascitic tap, what needs to be done?

	1 unit of red blood cells
	FFP till fibrinogen >1.5
	IV vitamin K till INR <1.5
	Nothing - the parameters are adequate
	1 pool of platelets

Dashboard

Overall score: **0%**

Question 91 of 204

□ □

A 31-year-old gentleman, with known ulcerative colitis, presents with a three-day history of profuse bloody diarrhoea. He reports opening his bowels up to 12 times each day and describes passing both bloody stool and frank blood.

On examination he is pale. His heart rate is 95 beats per minute, respiratory rate 16 breaths per minute, blood pressure 128/78 mmHg. His chest is clear to auscultation and his abdomen is soft but diffusely tender. The patient is ambulant and despite his diarrhoea appears relatively well.

The patient is diagnosed with a flare of his ulcerative colitis. Intravenous access is obtained and fluids and intravenous steroids given.

Admission bloods show:

Hb	102 g/l
Platelets	$556 \times 10^9/l$
WBC	$17.5 \times 10^9/l$
ESR	78 mm/h

Regarding his venous thromboembolism prophylaxis, what should happen during this admission?

	Compression stockings only
	No prophylaxis due to active bleeding
	Intermittent pneumatic compression devices
	Prophylactic dose low molecular weight heparin and compression stockings
	Treatment dose low molecular weight heparin and compression stockings

Overall score: **0%**

□ Question 92 of 204

□ □

A 42-year-old lady with known longstanding Crohn's disease was referred to the gastroenterology clinic. She presented to her GP with an 8-month history of tiredness. Since then she has developed loose stools with vague persistent abdominal pains with bloating and weight loss of approximately 4kg over the corresponding period. Her symptoms were initially attributed to irritable bowel syndrome but despite a trial of mebeverine 135mg TDS and loperamide 2mg PRN her symptoms persisted. She stated that her Crohn's disease was well controlled for several years with mesalazine 500mg TDS. In addition to Crohn's disease, she also had a past medical history of asthma and eczema for which she was prescribed mesalazine, Clenil modulite 200mcg BD, salbutamol PRN and Diprobase cream. She consumes 28 units of alcohol per week and is a non-smoker.

On examination, she appeared pale but otherwise well. She had a temperature of 37.3°C, a heart rate of 88/min and a blood pressure of 122/78 mmHg. Examination of the cardiovascular and neurological system was unremarkable. Examination of the gastrointestinal system likewise was unremarkable with no organomegaly and a soft non-tender abdomen.

Investigations revealed the following results:

Hb	86 g/l
MCV	112 fl
Platelets	342 * 10 ⁹ /l
WBC	7.2 * 10 ⁹ /l
TSH	1.96 u/l
B12	64 ng/l (160-900)
Folate	28 mcg/l (3-20)

Gastroscopy: normal appearance

Colonoscopy: normal appearance

Capsule endoscopy: jejunal strictures and fistulae

Schilling test: Prior to administration of intrinsic factor 1% B12 isotope excreted

Post-administration of intrinsic factor 1% B12 isotope excreted

What is the most likely diagnosis?

	Bacterial overgrowth
	Blind loop syndrome
	Pernicious anaemia
	Terminal ileal disease
	Vegan diet

Since then she has developed loose stools with vague persistent abdominal pains with bloating and weight loss of approximately 4kg over the corresponding period. Her symptoms were initially attributed to irritable bowel syndrome but despite a trial of mebeverine 135mg TDS and loperamide 2mg PRN her symptoms persisted. She stated that her Crohn's disease was well controlled for several years with mesalazine 500mg TDS. In addition to Crohn's disease, she also had a past medical history of asthma and eczema for which she was prescribed mesalazine, Clenil modulite 200mcg BD, salbutamol PRN and Diprobase cream. She consumes 28 units of alcohol per week and is a non-smoker.

On examination, she appeared pale but otherwise well. She had a temperature of 37.3°C, a heart rate of 88/min and a blood pressure of 122/78 mmHg. Examination of the cardiovascular and neurological system was unremarkable. Examination of the gastrointestinal system likewise was unremarkable with no organomegaly and a soft non-tender abdomen.

Investigations revealed the following results:

Hb	86 g/l
MCV	112 fl
Platelets	342 * 10 ⁹ /l
WBC	7.2 * 10 ⁹ /l
TSH	1.96 u/l
B12	64 ng/l (160-900)
Folate	28 mcg/l (3-20)

Gastroscopy: normal appearance

Colonoscopy: normal appearance

Capsule endoscopy: jejunal strictures and fistulae

Schilling test: Prior to administration of intrinsic factor 1% B12 isotope excreted

Post-administration of intrinsic factor 1% B12 isotope excreted

What is the most likely diagnosis?

	Bacterial overgrowth
	Blind loop syndrome
	Pernicious anaemia
	Terminal ileal disease
	Vegan diet

□ Question 93 of 204

□ □

A 42-year-old man presents to the emergency department due to bleeding from hair follicles on his head. He has also noticed that he has been off his food and losing weight. He is currently homeless after having been made redundant from his job one year ago. He is alcohol dependent with 30-units per week of hard liquor. He is not confused.

He has a past medical history of tuberculosis, for which he completed treatment six months. This treatment finished two months ago. On examination, he appears unkempt with poor oral hygiene and gingivitis. He has global muscle weakness rated at 4+/5 on the MRC scale. There is no sensory impairment. What is the most likely diagnosis?

	Pellagra
	Scurvy
	Beriberi
	Wernicke-Korsakoff syndrome
	Recurrence of tuberculosis

Question 94 of 204

A 21-year-old female presents for the first time with crampy right iliac fossa pain and diarrhoea. Colonoscopy shows patchy erythema in what appears to be a cobblestone appearance in her caecum and terminal ileum. She refuses to take prednisolone as her mother had taken it previously and had some particularly 'nasty' side-effects.

What is the next best agent to offer?

	Mercaptopurine
	Budesonide
	Azathioprine
	Methotrexate
	Infliximab

□ Question 2 of 110

□ □

A 32-year-old patient who is 10 weeks pregnant attends for her antenatal booking clinic. This is her first pregnancy, and she tells you she has been feeling lethargic and has a poor appetite. She has no past medical history of note.

On examination, she looks pale and appears comfortable at rest. Her chest is clear, heart sounds I&II are present and her abdomen is soft non-tender. She has some oedema of both ankles bilaterally. Her blood pressure is 111/75 mmHg and her heart rate is 79/min.

Investigations in clinics are as follows:

Hb	94 g/l
MCV	69 fl
Platelets	$168 \times 10^9/l$
WBC	$9.1 \times 10^9/l$
Hb electrophoresis	positive HbA2
Rhesus	negative
Blood Group	AB

Na ⁺	139 mmol/l
K ⁺	3.9 mmol/l
Urea	7.6 mmol/l
Creatinine	99 μ mol/l

What is the single most likely underlying condition?

	Alpha thalassaemia trait

	Beta thalassaemia trait
	Beta thalassemia major
	Iron deficiency anaemia
	Sideroblastic anaemia

Question 5 of 110

□ □

A 26-year-old gentleman presents to haematology clinic one week prior to starting chemotherapy for acute myeloid leukaemia (AML). He is currently feeling fatigued, suffering from night sweats, and has chronic lower back pain. He is anxious to start treatment. His past medical history includes ankylosing spondylitis and a clavicular fracture. His current medications include paracetamol and ibuprofen.

Blood tests:

Hb	113 g/l
Platelets	$156 \times 10^9/l$
WBC	$57 \times 10^9/l$
Na ⁺	140 mmol/l
K ⁺	3.6 mmol/l
Urea	4.2 mmol/l
Creatinine	63 μ mol/l

What measure is the least useful to prevent tumour lysis syndrome?

	IV fluids prior to chemotherapy
	Urine alkalization
	Prophylactic allopurinol
	Prophylactic rasburicase
	Stopping NSAID use

Question 7 of 110

You are looking after a 76-year-old man on an orthogeriatric ward. He is day 7 post dynamic hip screw for neck of femur fracture. He appears to be doing relatively well, but the nurse has noticed that he has a dark black necrotic looking skin over his left iliac fossa, and has asked you to come and look at it.

His past medical history includes hypertension, mild chronic kidney disease and atrial fibrillation.

He is currently on Ramipril 2.5mg once daily, Bisoprolol 5mg once daily, and treatment dose Clexane (patient was on Warfarin pre-operatively).

Pre-admission operative bloods:

Hb	142 g/l
Platelets	$212 \times 10^9/l$
WBC	$14.1 \times 10^9/l$

Na ⁺	138 mmol/l
K ⁺	4.6 mmol/l
Urea	8.2 mmol/l
Creatinine	167 μ mol/l

Bloods yesterday:

Hb	112 g/l
Platelets	$27 \times 10^9/l$
WBC	$10.1 \times 10^9/l$

Na ⁺	136 mmol/l
-----------------	------------

K ⁺	4.0 mmol/l
Urea	9.1 mmol/l
Creatinine	182 µmol/l

What should you do with regards to his Clexane?

	Stop Clexane and give Warfarin (target INR 2-3)
	Stop Clexane and give treatment dose Argatroban
	Switch treatment dose Clexane to Unfractionated Heparin infusion
	Give 1 pool of platelets
	Switch treatment dose Clexane to prophylactic Clexane

Dashboard

□ Question 8 of 110

A 76-year-old man presented with shortness of breath to the emergency department. On the basis of a recent knee replacement operation and unremarkable chest x-ray a CT pulmonary angiogram was performed and demonstrated a segmental pulmonary embolus with evidence of mild right heart strain. The patient was haemodynamically stable and required only minimal supplemental oxygen therapy.

The patient had known chronic kidney disease stage IV secondary to type 2 diabetes and hypertension. Treatment was therefore initiated with an intravenous unfractionated heparin infusion.

The patient's condition was stable over the following week with warfarin loading cautiously started at day 6 of admission. Routine blood tests at this point indicated a new abnormality in full blood count leading to further investigations as detailed below.

Haemoglobin	14.5 g / dL
White blood cells	8.6×10^3 / microlitre
Neutrophils	4.5×10^3 / microlitre
Lymphocytes	2.1×10^3 / microlitre
Platelets	67×10^3 / microlitre
Mean cell volume	85 fL
Mean cell haemoglobin	30.1 pg
B12	252 pmol / L
Folate	20 nmol / L

Heparin induced thrombocytopenia antibodies: positive (high titre)

Following cessation of IV heparin infusion, what is the appropriate management of the patient's thrombocytopenia?

	Bivalirudin

	Enoxaparin
	Warfarin
	Tirofiban
	Platelet transfusion

Dashboard

Overall score: **0%**

□ Question 9 of 110

You are asked to review a 75-year-old lady on the surgical ward. She has malignant carcinoma of the colon and had a large bowel resection seven days ago. Despite being on dalteparin since admission, she had developed a right-sided deep venous thrombosis (DVT). She tells you she had a similar problem ten years ago and had to take 'blood-thinning injections' for several months.

On examination she looks well with no signs of respiratory distress. Her oxygen saturations are 99% on room air and on auscultation she has vesicular breath sounds throughout both lung fields.

Her pre-operative blood tests are as following:

Hb	119 g/l	Na ⁺	135 mmol/l	Bilirubin	12 mol/l
Platelets	457 * 10 ⁹ /l	K ⁺	4.5 mmol/l	ALP	111 u/l
WBC	6.8 * 10 ⁹ /l	Urea	4.9 mmol/l	ALT	45 u/l
Neuts	4.0 * 10 ⁹ /l	Creatinine	81 µmol/l	γGT	30 u/l
Lymphs	0.9 * 10 ⁹ /l			Albumin	34 g/l
Eosin	0.0 * 10 ⁹ /l				

Her blood results today are as follows:

Hb	105 g/l	Na ⁺	133 mmol/l	Prothrombin time	10.7 s
Platelets	77 * 10 ⁹ /l	K ⁺	4.1 mmol/l	APTT	27.5s
WBC	7.6 * 10 ⁹ /l	Urea	5.7 mmol/l	APTT ratio	45 u/l
Neuts	4.9 * 10 ⁹ /l	Creatinine	98 µmol/l	D-Dimer	>1000 ng/ml
Lymphs	1.1 * 10 ⁹ /l			Albumin	31 g/l
Eosin	0.1 * 10 ⁹ /l				

Which of the following represents the optimal management for this patient whilst she remains an inpatient?

	Warfarin
	Bivalirudin
	IV heparin infusion
	Plasma exchange
	Rivaroxaban

□ Question 10 of 110

□ □

A 64-year-old man referred by the emergency department has fluctuating confusion and a severe headache of 4-hour duration. His only past history is a deep vein thrombosis 3 months ago for which he takes rivaroxaban 20mg OD.

On examination, he is orientated to person but cannot recall the time or where he is. There is no evidence of head injury. Temperature is 36.5 degrees, pulse 90 bpm, blood pressure 149/80 mmHg. A brief examination of the peripheral nervous system elicits no abnormal signs and his pupils are size 3 and equal.

An urgent CT head shows blood in the ventricular system.

What is the best immediate management to limit the bleeding?

	Vitamin K 10mg IV
	Pooled platelets
	Prothrombin complex concentrate (PCC)
	Haemofiltration
	Fresh frozen plasma (FFP) 15mls/kg

Question 11 of 110

A 23-year-old medical student went to Uganda on his elective but has had to return to the UK early due to illness. He had been careful to take malaria prophylaxis and slept under a mosquito net. He was using primaquine due to previous intolerable side effects with doxycycline. He was complaining of central abdominal pain and had noticed jaundiced sclera in the few days prior to returning to the UK. There is no relevant past medical history and he takes no regular medication. He is a non-smoker and drinks 2-4 units of alcohol weekly.

Observations show a blood pressure of 110/73 mmHg and heart rate of 98 beats per minute. He is afebrile, has a respiratory rate of 16 per minute and oxygen saturations of 94% on room air.

On examination, he is pale and jaundiced with yellow sclera. There is no cyanosis. His chest sounds clear and heart sounds are normal with no added. The abdomen is soft, generally tender but with no guarding or peritonism. Bowel sounds are normal.

Bloods show the following:

Haemoglobin	86 g/L	Sodium	139 mmol/L
Platelets	188 $\times 10^9/L$	Potassium	3.6 mmol/L
White cell count	11.0 $\times 10^9/L$	Urea	3.0 mmol/L
Neutrophils	8.5 $\times 10^9/L$	Creatinine	62 micromol/L
Reticulocytes	11%	Albumin	34 g/L
CRP	7 mg/L	Bilirubin	67 micromol/L
ALT	21 iu/L		
Alkaline Phosphatase	40 iu/L		

Peripheral blood film:

- Heinz bodies seen with methyl violet staining.
- Bite and blister cells also present.

What is the most likely diagnosis?

	G6PD deficiency
	<i>Plasmodium falciparum</i> infection
	<i>Mycoplasma pneumoniae</i>
	Hereditary spherocytosis
	Lead poisoning

On examination, he is pale and jaundiced with yellow sclera. There is no cyanosis. His chest sounds clear and heart sounds are normal with nil added. The abdomen is soft, generally tender but with no guarding or peritonism. Bowel sounds are normal.

Bloods show the following:

Haemoglobin	86 g/L	Sodium	139 mmol/L
Platelets	188 $\times 10^9/L$	Potassium	3.6 mmol/L
White cell count	11.0 $\times 10^9/L$	Urea	3.0 mmol/L
Neutrophils	8.5 $\times 10^9/L$	Creatinine	62 micromol/L
Reticulocytes	11%	Albumin	34 g/L
CRP	7 mg/L	Bilirubin	67 micromol/L
ALT	21 iu/L		
Alkaline Phosphatase	40 iu/L		

Peripheral blood film:

- Heinz bodies seen with methyl violet staining.
- Bite and blister cells also present.

What is the most likely diagnosis?

	G6PD deficiency
	<i>Plasmodium falciparum</i> infection
	<i>Mycoplasma pneumoniae</i>
	Hereditary spherocytosis
	Lead poisoning

Question 11 of 110

A 23-year-old medical student had been careful to take medication without any intolerable side effects with the exception of a rash in the few days prior to returning to his medication. He is a non-smoker.

Observations show a blood pressure of 120/80 mmHg and a respiratory rate of 16 per minute.

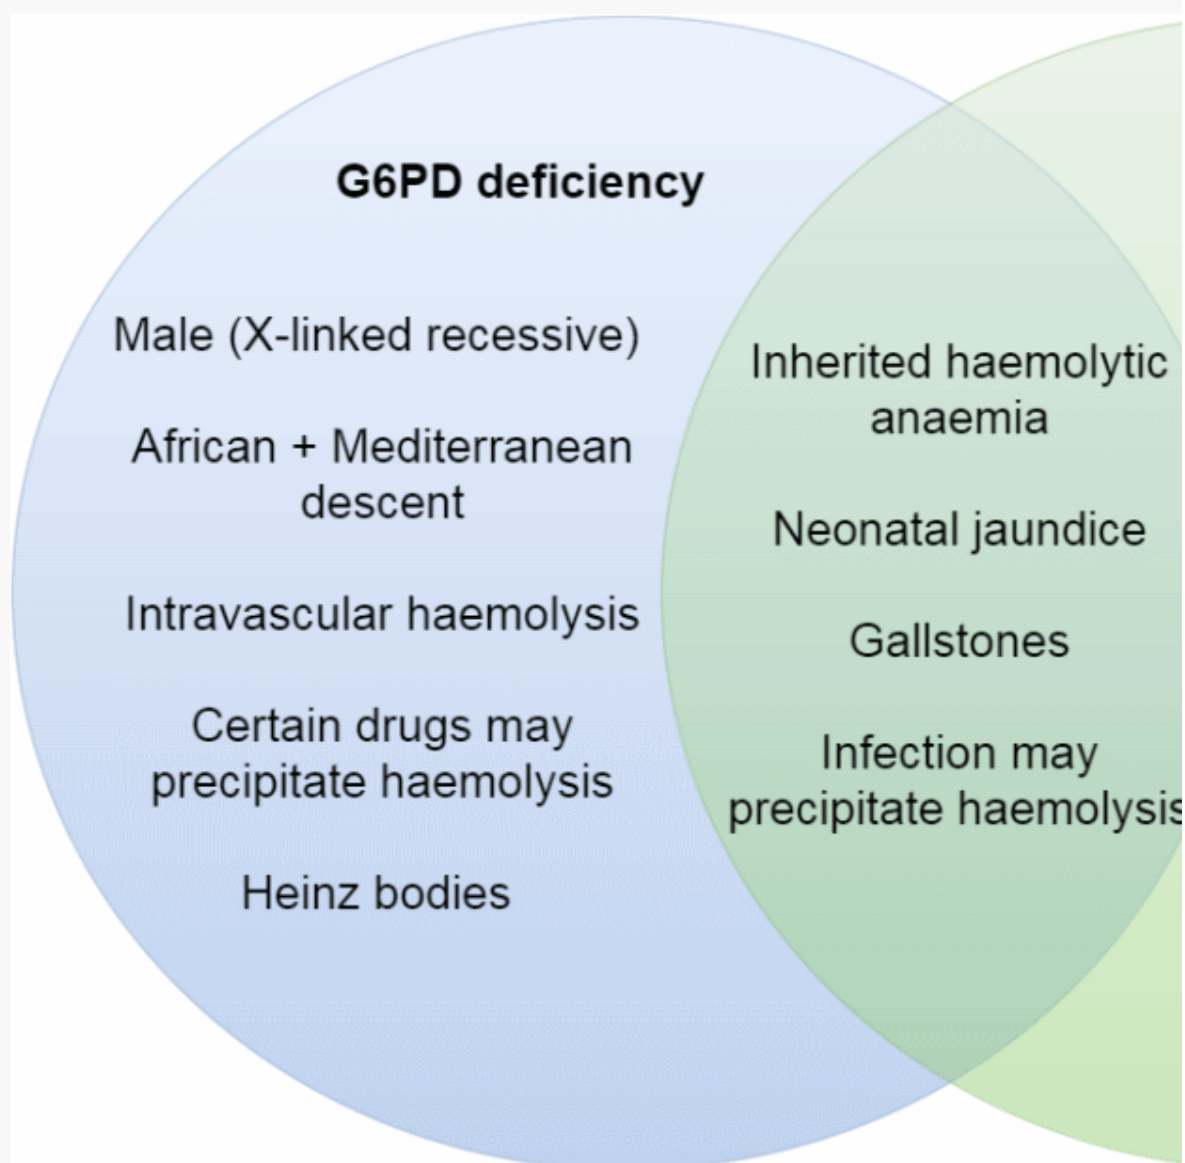

On examination, he is pale and has a mild fever. Heart sounds are normal with nil murmurs. Lung sounds are normal.

Bloods show the following:

Haemoglobin	86 g/L		
Platelets	$188 \times 10^9/L$	Potassium	3.6 mmol/L
White cell count	$11.0 \times 10^9/L$	Urea	3.0 mmol/L
Neutrophils	$8.5 \times 10^9/L$	Creatinine	62 micromol/L
Reticulocytes	11%	Albumin	34 g/L
CRP	7 mg/L	Bilirubin	67 micromol/L
ALT	21 iu/L		
Alkaline Phosphatase	40 iu/L

Question 12 of 110

A 42-year-old man with no past medical history of note and on no medications presents with complaints of dark-red urine during the night or early morning. His urine becomes clear during the day. He is otherwise asymptomatic. Urine dipstick is positive for blood but microscopy comes back as not showing any red blood cells. Clinical examination is unremarkable. His blood profile shows a mild macrocytic anaemia with an elevated reticulocyte count and he has an International Normalised Ratio (INR) of 7. Which of the following should be included in your management of the suspected condition?

<input type="checkbox"/>	Warfarin
<input type="checkbox"/>	Tranexamic acid
<input type="checkbox"/>	Imatinib
<input type="checkbox"/>	Aspirin
<input type="checkbox"/>	Splenectomy

Question 13 of 110

A 7-year-old girl who has recently emigrated from Turkey is brought to the Emergency Department with pain on walking and multiple swellings over her head. She also complains of persistent headaches which are now quite distracting and causing her to miss school. This symptoms have been getting gradually worse for the past few weeks.

She has a past medical history of eczema and asthma which is well controlled with a salbutamol inhaler as required. There is no family history of similar problems.

On examination a number of soft tissue swellings are noted on the scalp. She also has non-specific tenderness over the proximal part of the left femur.

A skull x-ray is requested:

□ Question 14 of 110

A 30-year-old man with acute myeloid leukaemia receives a bone marrow transplant from a matched unrelated donor.

7 days post-transplant, he develops a non-blanching purpuric rash over both legs. The rash is not itchy or scaly.

His heart rate 98/min and his blood pressure is 124/72 mmHg. His temperature is 37.3 °C and he is otherwise asymptomatic.

Blood tests are as follows:

Hb	89 g/l	Na ⁺	138 mmol/l
Platelets	9 * 10 ⁹ /l	K ⁺	3.2 mmol/l
WBC	0.8 * 10 ⁹ /l	Urea	4 mmol/l
Neuts	0.2 * 10 ⁹ /l	Creatinine	62 µmol/l
CRP	10 mg/l		

What is the most likely cause for the rash?

	Fungal infection
	Graft vs host disease
	Henoch Schonlein purpura
	Meningitis
	Thrombocytopenia

□ Question 15 of 110

A 44 year old male presents with a 2 month history of increasing lethargy. His wife reports him to be not quite himself for the past 2 months now, with poor oral intake and poor appetite. He is a self-employed software engineer but currently is unable to work due to his lethargy. He was previously treated for Hodgkin's lymphoma 5 years ago and has since been in remission.

On examination, he has no conjunctival pallor, is dry on his mucous membranes and extremely lethargic. Firm, rubbery lymph nodes are noted in the right axilla. Cardiovascular examination reveals a soft systolic murmur, respiratory and abdominal examinations are unremarkable. He is a non-smoker and drinks alcohol only occasionally. His blood tests are as follows:

Hb	8.8 g/dl
MCV	104 fl
Platelets	$94 \times 10^9/l$
WBC	$12.8 \times 10^9/l$
Red cell distribution	9% (normal 11.5-14.5%)
Blood film	leucoerythroblastic with myeloblasts

What is the cause of this patients anaemia?

	B12 and folate deficiency
	Iron deficiency
	Anaemia of chronic disease
	Myelodysplasia post-chemotherapy
	Marrow infiltration

□ Question 16 of 110

A 60-year-old man is seen in the ambulatory care clinic with a two week history of reduced urine output. This has been associated with a general malaise and fatigue. He denies any fever, abdominal pain, dysuria or change in flow. He has a past history of multiple myeloma, hypertension and benign prostatic hypertrophy. He has been on lenalidomide and dexamethasone chemotherapy for the last four months and was told at a clinic appointment one month ago that there were no problems with his blood results. His other medications are ramipril, finasteride and tamsulosin, and these have not been altered in many years.

On examination he appears fatigued and pale. His abdomen is soft with no palpable masses.

His investigation results are as follows:

Urine dip:

Blood	-
Protein	++
Ketones	-
Leucocytes	+
Nitrites	-

Blood tests:

Hb	110 g/l
Platelets	$130 \times 10^9/l$
WBC	$9 \times 10^9/l$

Na ⁺	139 mmol/l
K ⁺	4.7 mmol/l

Urea	10 mmol/l
Creatinine	184 µmol/l
Ca ²⁺	2.3 mmol/l

Which investigation is most likely to reveal the cause of his renal failure?

	Blood film
	Mid-stream urine
	Serum free light chains
	Serum protein electrophoresis
	Ultrasound renal tract

□ Question 17 of 110

A 22-year-old man with sickle cell disease is seen in the Emergency Department. He has had worsening pain in his arms and legs for the last 2 days and 5 hours ago developed a painful sustained erection.

He has felt otherwise well recently and has no other past medical history. He is on regular paracetamol, ibuprofen, folate and penicillin. He does not receive regular transfusions and has been admitted with a crisis only once before. He has never had an episode of painful sustained erection.

On examination he has a heart rate of 110 beats per minute and a blood pressure of 132/95 mmHg. His oxygen saturations are 96% on room air and he is afebrile. His chest is clear and abdomen is soft. He has no swelling or erythema of his limbs, though they are generally tender. He continues to have an erection, though there is no sign of ischaemia.

His chest x-ray shows clear lung fields.

His blood tests are as follows:

Hb	78 g/l	Na ⁺	141 mmol/l
Platelets	331 * 10 ⁹ /l	K ⁺	3.7 mmol/l
WBC	9 * 10 ⁹ /l	Urea	5 mmol/l
Neuts	7 * 10 ⁹ /l	Creatinine	86 µmol/l
Lymphs	1.6 * 10 ⁹ /l	CRP	14 mg/l

He is treated with intravenous fluids and generous analgesia with diamorphine. His limb pain is improved but he continues to have a painful erection.

What is the next most appropriate step?

	Adrenalin
	Diethylstilbestrol

	Exchange transfusion
	Review by urologist
	Sildenafil

Dashboard

Overall score: **0%**

□ Question 20 of 110

A 44 year old female patient is admitted to the oncology ward to undergo chemotherapy for Diffuse Large B-Cell lymphoma stage IVb. She had originally presented to her GP with intermittent abdominal bloating and constipation and occasional shortness of breath. She also reported having to often get up in the middle of the night to change the bed clothes due to drenching sweats. Her GP had been concerned by these symptoms and had organised an immediate chest X-ray to be undertaken at the nearby hospital.

Chest X-ray

- large mediastinal mass with clear lung fields.

On receiving this report the GP arranged an urgent appointment with a local haematologist as he suspected that the patient was suffering from lymphoma. She was seen only 4 days later. Given the clinical history the team at the hospital arranged some urgent investigations.

Hb	9.5 g/dl
Platelets	$140 \times 10^9/l$
WBC	$36.5 \times 10^9/l$
Lactate Dehydrogenase	2540IU/l

CT-guided Lymph node biopsy

- cells are large, with prominent nucleoli and abundant cytoplasm and many mitoses expressing CD19 and CD20 markers

PET scan

- large extra-nodal disease bulks most notable in the ileo-caecal area and in the mediastinum. Overall bulky disease in keeping with the diagnosis of advanced stage lymphoma.

The patient is admitted to receive cycle one of R-CHOP chemotherapy under close monitoring.

What electrolyte abnormalities would suggest tumour lysis syndrome?

	High Potassium, high Calcium, low Phosphate
	Low Potassium, high Calcium, low Phosphate
	High Potassium, low Calcium, high Phosphate
	Low Potassium, low Calcium, high Phosphate
	Low Potassium, low Calcium, low Phosphate

□ Question 21 of 110

A 65-year-old female, known to have metastatic breast carcinoma presents to the hospital with a 24-hour history of increasing pain, swelling and erythema of her right calf. She is otherwise relatively well. She was diagnosed with breast carcinoma four years previously and was initially treated with surgery, radiotherapy and chemotherapy. She was found to have disease recurrence with distant metastasis 12 months previously. She is known to have liver and bone metastases.

On examination, she appears pale and has some hair loss following recent chemotherapy. Apart from her swollen, erythematous, tender right calf and a fentanyl patch examination is unremarkable.

Bloods on admission show:

Hb	100 g/l
Platelets	$180 \times 10^9/l$
WBC	$7.2 \times 10^9/l$
D-Dimer	1276 $\mu\text{g/L}$ (normal $<500\mu\text{g/L}$)

Na^+	132 mmol/l
K^+	4.5 mmol/l
Urea	7.2 mmol/l
Creatinine	110 $\mu\text{mol/l}$

She is diagnosed with a right leg deep vein thrombosis. Given her current clinical condition, what is the best method of anticoagulation?

	Low molecular weight heparin (LMWH) and warfarin until warfarin therapeutic followed by warfarin therapy for six months then reassess.

	Low molecular weight heparin (LMWH) for three months then reassess.
	Warfarin therapy starting with a slow loading regime for six months then reassess.
	Low molecular weight heparin (LMWH) for six months then reassess.
	Referral for inferior vena cava filter insertion

□ Question 22 of 110

A 57 year old female presents to pre-assessment surgical clinic prior to an elective arthroscopy of her left knee that she injured while playing tennis. She is otherwise asymptomatic, has no other medical history and is a lifelong non-smoker. She drinks 10 units of alcohol per week. Recently, she has experienced hot flushes and irregular periods, which she puts down to undergoing the menopause. Examination of her cardiovascular, respiratory and abdominal systems are unremarkable.

Her blood results are as follows:

Hb	9.5 g/dl
MCV	59 fl
Platelets	$389 \times 10^9/l$
WBC	$4.5 \times 10^9/l$
Red cell distribution width	13% (normal range 11.5-14.5%)
Blood film	anisocytosis, hypochromia, target cells

Which investigation is most likely to reveal the diagnosis?

	Serum ferritin
	Total iron binding capacity
	Serum iron
	Haemoglobin electrophoresis
	Bone marrow biopsy

Overall score: **0%**

□ Question 23 of 110

A 72-year-old lady is admitted with a tonic-clonic seizure. She was initially treated with two doses of 10mg diazepam however she failed to respond. She was then prescribed a loading dose of intravenous phenytoin and then prescribed maintenance dose phenytoin. Past medical history included a previous stroke, gallstones and hypertension. Drug history included clopidogrel, amlodipine, simvastatin. She recovered well and was discharged 6 days later.

Three weeks after her hospital admission she visits her GP accompanied by her husband complaining of feeling generally unwell and a rash. On examination she has a wide spread morbilliform eruption on most of her body and some mild right upper quadrant pain. The GP could palpate cervical and inguinal lymph nodes. Observations heart rate 110 regular, blood pressure 120/80, saturations 97% on air and temperature 38.2. The GP sends the patient to hospital for further tests. Bloods show:

Hb	110 g/l
WCC	$14 \times 10^9/l$
Neutrophils	$7.2 \times 10^9/l$
Eosinophils	$2.3 \times 10^9/l$
Platelets	$81 \times 10^9/l$
Na ⁺	141 mmol/l
K ⁺	4.3 mmol/l
Creatinine	101 μ mol/l
Urea	6.8 mmol/l
Bilirubin	22 μ mol/l
Alk phos	80 u/l
ALT	150 u/l
Albumin	32 g/l
INR	1.1

What is the most likely diagnosis?

	Lymphoma
	DRESS syndrome
	Cholecystitis
	EBV
	Meningococcal septicaemia

□ Question 23 of 110

A 72-year-old lady is admitted with a tonic-clonic seizure. She was initially treated with two doses of 10mg diazepam however she failed to respond. She was then prescribed a loading dose of intravenous phenytoin and then prescribed maintenance dose phenytoin. Past medical history included a previous stroke, gallstones and hypertension. Drug history included clopidogrel, amlodipine, simvastatin. She recovered well and was discharged 6 days later.

Three weeks after her hospital admission she visits her GP accompanied by her husband complaining of feeling generally unwell and a rash. On examination she has a wide spread morbilliform eruption on most of her body and some mild right upper quadrant pain. The GP could palpate cervical and inguinal lymph nodes. Observations heart rate 110 regular, blood pressure 120/80, saturations 97% on air and temperature 38.2. The GP sends the patient to hospital for further tests. Bloods show:

Question 24 of 110

A previously healthy 68-year-old male patient is referred by his GP to the general medical clinic. He has mixed symptoms of pain in multiple areas, including his upper arm, neck and legs. This has worsened over a period of months and seems not to have been helped with multiple analgesics, including paracetamol, codeine phosphate and ibuprofen. In this time the patient has also become increasingly short of breath.

A full work up is undertaken and the results are shown -

Hb	9.4 g/dl
Platelets	$174 \times 10^9/l$
WBC	$8.4 \times 10^9/l$

Na ⁺	136 mmol/l
K ⁺	4.7 mmol/l
Urea	8.4 mmol/l
Creatinine	125 μ mol/l
Corrected calcium	2.9mmol/l
Albumin	34g/L

Kappa light chains detected
Lambda light chains absent

IgG elevated
IgA normal
IgM normal

Urine Bence Jones proteins detected

Skeletal survey multiple osteolytic lesions seen throughout axial skeleton including on the right humerus, thoracic spine and both femurs.

Given the presumed diagnosis, what tests are most relevant for staging of the condition?

	Calcium, x-rays and creatinine
	Free light chain level
	Renal function
	B2-microglobulin and albumin
	Haemoglobin and albumin

Dashboard

Overall score: **0%**

□ Question 25 of 110

□ □

A 23-year-old woman is investigated for abdominal pain and haematuria. She started developing abdominal pain around 2 months ago and it is generally worse after eating. She also reports arthralgia, weight loss of 3kg and general lethargy.

On examination blood pressure is 150/102 mmHg, pulse 84/min and temperature 37.6°C. Dipstick examination of her urine shows blood+++.

Bloods show the following:

Na ⁺	142 mmol/l
K ⁺	4.9 mmol/l
Urea	8.9 mmol/l
Creatinine	123 µmol/l
CRP	73 mg/l

An angiogram is performed:

© Image used on license from Radiopaedia

What is the most likely diagnosis?

	Renal cell cancer
	Polyarteritis nodosa

	Henoch-Schonlein purpura
	Antiphospholipid syndrome
	Granulomatosis with polyangiitis

□ Question 26 of 110

You are the medical registrar on call. The surgical registrar contacts you for a patient he has just seen in clinic who requires an elective cholecystectomy. The patient is a 65-year-old woman who has atrial fibrillation for which she takes rivaroxaban. The patient is otherwise well. The bloods performed in clinic that day are as follows:

Hb	131 g/l
Platelets	352 * 10 ⁹ /l
WBC	5.5 * 10 ⁹ /l
INR	1.5

Na ⁺	137 mmol/l
K ⁺	3.6 mmol/l
Urea	3.2 mmol/l
Creatinine	67 µmol/l

The surgical registrar would like to know how long the patient should omit their anticoagulation before the procedure?

	1 day
	2 days
	3 days
	5 days
	7 days

Question 27 of 110

A 32 year old patient presents the acute medical unit with 6 hour history of worsening chest pain. Otherwise he mentions that he has been feeling generally more tired than normal recently, is more breathless than usual and has noticed some dark discolouration of his urine, especially in the mornings. He has a past medical history of deep vein thrombosis (DVT) in his left leg for which he had 6 months of warfarin therapy 2 years ago.

An immediate ECG is performed with shows anterior ST depression and T wave inversion.

CXR: nil acute

Blood tests:

Troponin I	1.02 µg/L (elevated)
Hb	102 g/l
Plt	101 x10 ⁹ /l
WCC	5.7 x10 ⁹ /l
Na+	136 mmol/l
K+	5.0 mmol/l
Urea	8 mmol/l
Creatinine	79 µmol/l

The patient is taken to the cath lab due to his cardiac sounding chest pain with ECG and cardiac enzyme abnormalities. The coronary angiogram shows a thrombosis of the left anterior descending artery, which is aspirated during the procedure. No significant atherosclerotic plaque formation or stenosis of the coronary arteries is identified.

Given this gentleman's presentation, which of the following investigations would be most useful to do next?

Anti cardiolipin antibodies

	Acid haemolysis test
	Antiphospholipid antibodies
	Factor V leiden levels
	Coombs' test

Dashboard

□ Question 28 of 110

A 40 year old man presents to the Emergency Department with non-specific symptoms of lethargy, malaise, headache, body aches, a low grade fever and a sore throat. Examination is essentially normal aside from multiple limb petechiae. Tympanic temperature is 37.6°C. Blood pressure, heart rate and pulse oximetry is normal.

Blood tests show:

Haemoglobin	112g/L	Sodium	136mmol/L
MCV	82fL	Potassium	4.5mmol/L
Platelets	$77 \times 10^9/L$	Urea	6.9mmol/L
White cells	$32 \times 10^9/L$	Creatinine	111mol/L
Prothrombin time	23secs	CRP	54mg/L
Fibrinogen	0.45g/L	HIV test	Negative
Liver enzymes	normal		

Automated counter is unable to supply differential white cell count.

Manual blood film shows immature granulocytes with bilobed nuclei and Auer rods.

What is the most important immediate therapy to institute?

	All trans retinoic acid (ATRA) [tretinoin]
	Methotrexate
	Imatinib
	Rituximab
	Arsenic trioxide

□ Question 29 of 110

A 67 year old female presents with 4 month history of increasing lethargy and malaise. She has no past medical history and travels widely, last visiting the Middle East one week prior to this admission, returning with a respiratory tract infection that appears to be resolving. She is a lifelong non-smoker and does not drink alcohol to excess. Over the past two weeks, she reports increasing bilateral persistent headache associated with binocular visual blurring. In addition, she describes a non-specific abdominal discomfort without any changes in bowel habit.

On examination, you note bilateral axillary lymphadenopathy and conjunctival pallor. Cardiovascular and respiratory system examinations were unremarkable. Neurological examination is unremarkable. Fundoscopy reveals dilated tortuous retinal veins. Abdominal examination reveals hepatosplenomegaly. Lastly, you note areas of purpura around her left anterior shin and her right upper arm. A chest radiograph is unremarkable.

Her blood results are as follows:

Hb	8.7 g/dl
MCV	79 fl
Platelets	$190 \times 10^9/l$
WBC	$3.4 \times 10^9/l$
Na ⁺	142 mmol/l
K ⁺	4.5 mmol/l
Urea	7.6 mmol/l
Creatinine	89 μ mol/l
Adj Calcium	2.47 mmol/l
Phosphate	1.34 mmol/l
LDH	1890 (normal range 140-280 units/L)
Serum electrophoresis	IgM paraprotein band at 5.4 g/L

A bone marrow biopsy demonstrates 14% infiltration of lymphoplasmacytic cells

What is the diagnosis?

	Waldenstrom's macroglobulinaemia
	Multiple myeloma
	Monoclonal gammopathy of unknown significance (MGUS)
	Chronic lymphocytic leukemia (CLL)
	Upper respiratory tract infection (URTI)

Dashboard

□ Question 30 of 110

A 75-year-old male presents following a fall whilst intoxicated. He has sustained a fractured right neck of femur and is admitted under the orthopaedic team. He has a past medical history of liver cirrhosis, ischaemic heart disease and congestive cardiac failure. There is a suspicion that he drinks excessively.

On examination, his right leg is externally rotated and shortened. He is thin and has mild pitting oedema to his mid-shins. His pulse is 92 beats per minute and regular, respiratory rate 18 breaths per minute, blood pressure 121/72 mmHg, SaO₂ 94% on room air. Apart from a slight expiratory wheeze, his chest is clear to auscultation.

Bloods show:

Hb	112 g/l
Platelets	48 * 10 ⁹ /l
WBC	11.2 * 10 ⁹ /l
INR	1.9

The orthopaedic team arrange for a transfusion of two units of fresh frozen plasma (FFP) and two units of platelets before taking the patient to theatre.

Four hours after the transfusion the patient has become unwell.

Observations show a respiratory rate of 34 breaths per minute, S_aO₂ 80% on room air. Heart rate is 120 beats per minute and regular. Temperature is 38.5°C. A chest X-ray is performed at the bedside which shows bilateral shadowing.

What is the most likely cause of the patient's deterioration?

	Community acquired pneumonia
	Transfusion associated circulatory overload
	Acute myocardial infarction
	Transfusion associated acute lung injury

	Atrial fibrillation with a rapid ventricular response

Question 34 of 110

A 34 year old male presents with a 4 day history of bloody diarrhoea and vomiting, fevers and associated with occasional abdominal cramps. He reports no other symptoms. He reports no previous history of gastrointestinal disease; there is no family history of inflammatory bowel disease. He has no past medical history except for a left knee arthroscopy following an injury playing football 7 months ago. He is a lifelong non-smoker, drinks 14 units of alcohol a month, has not travelled abroad in the past year and last ate outside of his home a week ago during a barbecue at his brothers house.

On examination, he appears dehydrated. There is mild generalised abdominal tenderness with increased bowel sounds. Respiratory and cardiovascular examinations were unremarkable. His blood tests are as follows:

Hb	9.2 g/dl
MCV	90fl
Platelets	$49 \times 10^9/l$
WBC	$14.2 \times 10^9/l$
Neutrophils	$12.8 \times 10^9/l$
Blood film	schistocytes, reticulocytosis
Direct antiglobulin test	negative
Urea	14.9 mmol/l
Creatinine	159 $\mu\text{mol/l}$
CRP	82 mg/l

What is the cause of this patients blood abnormalities?

<input type="checkbox"/>	Microangiopathic haemolytic anaemia
<input type="checkbox"/>	Cold autoimmune haemolytic anaemia
<input type="checkbox"/>	

	Warm autoimmune haemolytic anaemia
	Iron deficiency anaemia
	Acute myeloid leukemia

Question 35 of 110

□ □

A 26 year old female who is 14 days post-partum (spontaneous vaginal delivery) presents to your medical admissions unit with her partner who is worried that she is confused. She is unable to provide any history but her partner tells you that she has gradually gotten worse over the past few days. Her observations are as follows: temperature 38°C, pulse 90/min, blood pressure 154/88 mmHg, respiratory rate 16/min, sats 99% on room air.

On examination, she looks pale. Her chest is clear and abdomen is soft, non-tender. She has multiple bruises on her arms. Her blood results are pending.

What is the most likely diagnosis?

	Haemolytic uraemic syndrome
	Thrombotic thrombocytopenic purpura
	Idiopathic thrombocytopenic purpura
	Retained products of placenta
	Disseminated intravascular coagulation (DIC)

□ Question 36 of 110

□ □

An 85 year old male is referred by the anaesthetic registrar after abnormal blood test results were noted during pre-assessment for an elective hip replacement. He is other wise fit and well, independent with all activities of daily living and continues to drive. His past medical history includes diet controlled type 2 diabetes mellitus and hypertension. On examination, he is alert and well, reports no discomfort, pain, or non-specific malaise. No skin bruises or conjunctival pallor are noted. You note a rubbery, non-tender and firm 3cm lymph node in the left cervical chain and non-tender splenomegaly at 8cm below the costal margin. His chest is clear and normal heart sounds are noted. His blood tests are as follows, with blood tests from his GP 6 months ago in brackets:

Hb	8.9 (9.5) g/dl
Platelets	78 (76) * $10^9/l$
WBC	67 (32) * $10^9/l$
Blood film	mature lymphocytes and smudge cells

What is the appropriate treatment?

	Monitor and repeat blood count in 6 months
	Fludarabine, cyclophosphamide and rituximab treatment immediately
	Delayed chlorambucil treatment in 6 months
	Platelet transfusion
	Intravenous immunoglobulin

Dashboard

Question 37 of 110

A 72 year old male was admitted with 72 hours of progressive ascending motor weakness associated with palpitation and back pain. A diagnosis of Guillain-Barre syndrome was made and he was started on intravenous immunoglobulin (IVIg) with intensive monitoring on the neurology ward. You are asked to review the bloods of the patient on the fourth of five days of IVIg treatment. You note his sodium to have changes as follows: Na 145 → 141 → 134 → 130 → 126. The patient reports 'feeling better after the drip', denies any cough, shortness of breath, diarrhoea, nausea or vomiting. On examination, he appears comfortable in bed, JVP 2/3 cm above the angle of Louis, has warm peripheries and capillary refill time of 2 seconds. His chest is clear on auscultation, cardiovascular examination unremarkable and neurological examination unchanged from admission. What is your management plan?

	No action
	Intravenous fluid
	Fluid restrict to 1.5 litres
	Contact endocrinology team regarding possible syndrome of inappropriate anti-diuretic hormone (SIADH)
	Contact intensive care unit regarding escalation and intubation

Dashboard

□ Question 38 of 110

A 75-year-old man underwent a right hemicolectomy as radical treatment for a caecal adenocarcinoma. During the immediate post-operative period the patient was noted to be significantly confused and investigations to assess for a septic source were requested. Blood tests indicated new neutrophilia and thrombocytopenia. Noting that the patient had been started on enoxaparin for venous thrombosis prophylaxis on the first day after the operation, heparin induced thrombocytopenia antibodies were requested by the surgical junior team.

A specialist medical review was requested on day 6 post-operatively to assess the patient in the light of the results of these investigations. The patient was found to be back to his cognitive baseline and was starting to mobilise on the ward with the help of physiotherapy. Clinical examination was unremarkable except for the healing abdominal surgical incision.

Aside from his recent cancer diagnosis, the patient's past-medical history included only hypercholesterolaemia treated with simvastatin. He had no known allergies or drug sensitivities.

Blood result	Pre-operatively	Day 1 post-op	Day 4 post-op	Day 6 post-op
Platelets ($\times 10^3$ / microlitre)	175	95	125	141
Neutrophils ($\times 10^3$ / microlitre)	5.3	14.8	12.8	8.8
C-reactive protein (mg / L)	6	142	94	25
International normalised ratio	1.0	1.2	1.1	1.1

Chest x-ray: clear lung fields aside from minor bibasal atelectasis

Urine culture: no growth

CT abdomen: minimal abdominal free fluid, no evidence of focal collection, large bowel anastomoses intact

Heparin-induced thrombocytopenia antibodies: positive (moderate titre)

What is the likely cause for the patient's thrombocytopenia?

--	--

	Heparin induced thrombocytopenia
	Post-operative sepsis
	Post-operative thrombocytopenia
	Thrombotic thrombocytopenic purpura
	Disseminated intravascular coagulation

Question 39 of 110

□ □

A 62-year-old gentleman is seen at the respiratory clinic after a mass lesion is identified by his GP on chest x-ray. He is a heavy smoker and has had a cough and weight loss for the past two months. On further questioning, he admits to feeling very weak and is having difficulty getting out of a chair. On examination, the consultant notices some proximal muscle wasting. Initial investigations reveal a blood pressure of 170/90mmHg and a low potassium. In addition to organising staging CT and bronchoscopy, he requests a 24-hour urinary cortisol test, which is raised.

Which of the following is the most likely underlying pathology?

	Squamous cell bronchial carcinoma
	Large cell bronchial carcinoma
	Carcinoid tumour
	Small cell bronchial carcinoma
	Bronchial adenocarcinoma

Question 40 of 110

□ □

A 68-year-old gentleman with known chronic lymphocytic leukaemia (CLL) is reviewed in the Haematology Clinic.

He is normally an active gentleman who enjoys playing golf 3 times per week, but he complains that he has been feeling increasingly fatigued since his last appointment 6 months previously. He states that he has not been able to play golf for several weeks and his wife tells you that he has started napping during the afternoons. His past medical history is otherwise unremarkable and he takes no regular medications.

Examination reveals a tired gentleman with marked axillary and inguinal lymphadenopathy. His abdomen is soft with mild upper abdominal tenderness. A liver edge is palpable 3cm below the costal margin and his spleen is markedly enlarged.

His full blood count today is as follows:

Hb	114 g/l
Platelets	$173 \times 10^9/l$
WBC	$30.4 \times 10^9/l$
Neutrophils	$5.8 \times 10^9/l$
Lymphocytes	$23.1 \times 10^9/l$

His lymphocyte count 2 months ago was $15.3 \times 10^9/l$ and a decision to start the patient on fludarabine, cyclophosphamide, and rituximab (FCR) chemotherapy is taken.

Given the proposed treatment strategy, which of the following prophylactic medications is it most important to start?

	Co-trimoxazole
	Aciclovir
	Entecavir
	Fluconazole

	Penicillin V

Question 41 of 110

A 33-year-old patient presents to the emergency department feeling very lethargic and tired over the last week. He has been increasingly short of breath on exertion and his exercise tolerance has fallen to a few hundred yards before he is out of breath. He is a known sickle cell disease patient who is managed by the Haematology team in your hospital. On examination he is afebrile and heart rate and blood pressure are within normal limits. His respiratory rate is 16/min and his oxygen saturation is 98% on air. He does become noticeably short of breath on minimal movement.

His blood tests show:

Hb	65 g/l
Platelets	$46 \times 10^9/l$
WBC	$2.5 \times 10^9/l$
Neuts	$1.2 \times 10^9/l$
Haptoglobins	1.9 g/L (0.3-2.0)
Reticulocytes	$8.9 \times 10^9/L$ (25-80)

Na ⁺	136 mmol/l
K ⁺	3.9 mmol/l
Urea	7.4 mmol/l
Creatinine	78 μ mol/l
CRP	<3 mg/L(<10)
LDH	200 IU/L (200-500)

Bilirubin	4 μ mol/l
ALP	89 u/l
ALT	34 u/l

Albumin	39 g/l

His chest x-ray is normal.

On further questioning, he tells you that his 5-year-old daughter was unwell 3 weeks ago. He took her to see the GP and was told it was likely to be a viral illness. What is the most likely cause for his blood results as shown?

	Parvovirus B19
	Acute chest crisis
	Splenic sequestration
	HIV
	Legionella pneumoniae

□ Question 43 of 110

A 16-year-old female was admitted with new onset facial swelling. The facial swelling started 45 minutes ago and initially involved her lips. She complained of a sensation of choking and a feeling of being unable to speak with hoarseness of her voice. She had been investigated on multiple occasions for abdominal pain and was diagnosed with non-specific abdominal pain. She was not taking any medication and was otherwise healthy prior to the admission.

She was given prednisolone 40mg PO and chlorpheniramine 10mg PO and admitted for observation. Whilst in the department she developed profound shortness of breath with associated stridor. Her swelling around her lips worsened and involved the whole of her face. On examination, she was in respiratory distress with severe biphasic stridor. Her respiratory rate was 32/min with an oxygen saturation of 88% on air. Auscultation of her chest also revealed the presence of a widespread polyphonic wheeze. Examination of her cardiovascular system revealed the presence of flushed peripheries with a bounding peripheral pulse. Her pulse was 102bpm and her blood pressure was 92/68 mmHg. Her GCS was 15 and neurological and abdominal examinations were unremarkable. She was cannulated and commenced on stat intravenous colloid solution. She was given adrenaline 0.5mg IM on three separate occasions within 10 minutes with no improvement. She was transferred immediately to the Intensive Care Unit and an anaesthetist fast bleeped to secure her airway.

What is the best immediate management step pending definitive airway management?

	Commence IV adrenaline infusion
	Commence danazol
	Commence IV dopamine
	Commence fresh frozen plasma infusion
	Commence C1 esterase inhibitor concentrate infusion

□ Question 47 of 110

A 33 year old female presents to urgent care centre complaining of 4 days of increasing lethargy and reduced exercise tolerance. In addition, she reports dark urine but no other symptoms. She normally works as a clerical member of staff in the same hospital. Her only past medical history is ulcerative colitis, which before a flare 2 weeks ago requiring addition of sulphasalazine, had been well controlled with no immunosuppressants. On examination, you note conjunctival pallor bilaterally. Her abdomen is soft and non-tender. Her respiratory, cardiovascular and neurological examinations are unremarkable except for a mild systolic murmur and sinus tachycardia of 104 beats/ minute. Rectal examination was empty, no oral ulcers were noted.

Her blood tests are as follows:

Hb	8.9 g/dl
MCV	85fl
Platelets	$356 \times 10^9/l$
WBC	$12.1 \times 10^9/l$
Blood film	Heinz bodies, reticulocytosis
CRP	30 mg/l
LDH	2400 u/l

What is the most appropriate immediate treatment?

	Transfuse 2 units of packed red blood cells
	Start intravenous hydrocortisone, stop sulphasalazine
	Start intravenous hydrocortisone, continue sulphasalazine
	Stop sulphasalazine only
	Urgent colonoscopy

□ Question 48 of 110

A 70-year-old man is referred to the haematology clinic by his general practitioner with anaemia. He has experienced progressive fatigue and shortness of breath for four months. On further questioning he also describes waking up at night soaked in sweat on one or two nights per week for the last month. His weight is stable. He has a past medical history of hypertension and COPD.

On examination he is pale. His heart sounds are normal and his chest is clear.. He has no ankle oedema and JVP is not raised. His abdomen is soft and he has splenomegaly 3cm below the costal margin with no hepatomegaly.

Test results sent with him by his GP are as follows:

Hb	92 g/l	Na ⁺	143 mmol/l
Platelets	143 * 10 ⁹ /l	K ⁺	3.7 mmol/l
WBC	4 * 10 ⁹ /l	Urea	7 mmol/l
Neuts	2 * 10 ⁹ /l	Creatinine	86 µmol/l
Lymphs	1 * 10 ⁹ /l	CRP	5 mg/l

Blood film: Anisocytosis with mild hypochromia. Tear drop cells. Mild thrombocytopenia with no platelet clumping.

Chest x-ray: Mildly hyperexpanded lung fields. No focal consolidation. No masses or lymphadenopathy.

Upper GI endoscopy & colonoscopy: Normal

Presence of which mutation is required to confirm the likely diagnosis?

	BCR-ABL
	BCL2
	C-MYC

	JAK2
	TP53

Question 49 of 110

A 23 year old male of Nigerian descent is referred from the ED with acute shortness of breath associated with fever and dry cough. His shortness of breath has limited him to an exercise tolerance of around 10 yards. He also complains of excruciating right sided chest pain. He is known to have sickle cell anaemia and has had no admissions to the hospital in the last 3 years.

Observations

- heart rate 94bpm regular
- blood pressure 112/74 mmHg
- temperature 38.3
- respiratory rate 22
- urine output under 30ml/hr
- oxygen saturations 93% on room air

Examination

- respiratory system shallow breathing, bronchial breath sounds with crepitations to right base

Blood results:

Hb	7.7 g/dl
Platelets	200 * 10 ⁹ /l
WBC	13.2 * 10 ⁹ /l

Bilirubin	36 µmol/l
Urea	8.2 mmol/l
Creatinine	146 µmol/l

What is the most important initial steps in management?

	Oxygen, IV fluids, antibiotics and analgesia
	2 unit blood transfusion and analgesia
	Oxygen and analgesia only
	Antibiotics and IV fluid only
	Plasmapheresis and analgesia

Question 50 of 110

□ □

A 51-year-old man presents with dysuria and a low grade fever. He is prescribed a course of Nitrofurantoin for a suspected urinary tract infection. He has a history of ischaemic heart disease for which he takes aspirin and atorvastatin. The following day, he notices that his urine has become very dark and he feels breathless and more unwell.

Bloods show:

Hb	78 g/L
WCC	$14.1 \times 10^9/\text{L}$
Neutrophils	$13 \times 10^9/\text{L}$
Platelets	$280 \times 10^9/\text{L}$
Bilirubin	87 mg/dL
ALT	45 IU/L
Alkaline phosphatase	73 IU/L
Urea	5 mmol/L
Creatinine	80 $\mu\text{mol/L}$

Blood film microscopy comments on the presence of Heinz bodies. What is the underlying diagnosis?

	Hereditary spherocytosis
	Paroxysmal nocturnal haemoglobinuria
	Haemolytic uraemic syndrome
	Urinary sepsis secondary to <i>E. coli</i>
	Glucose-6-phosphate dehydrogenase deficiency (G6PD)

□ Question 51 of 110

A 70 year-old woman presents with severe back pain which has been worsening over the last month. Prior to this she has never suffered from back pain. She has been lethargic, and her husband notes some intermittent confusion. A systemic enquiry reveals long standing exertional breathlessness, and constipation. She has no other bowel or bladder disturbance.

Her background includes chronic obstructive pulmonary disease, which is managed by her GP. She gave up smoking two years ago. Her well woman check up 12 months ago was entirely normal, aside from a slightly raised cholesterol which is being management with diet.

On examination, she has a normal gait. There is some mild tenderness over L3/L4 vertebra with no lower limb neurological deficit. Cardiorespiratory examination reveals an ejection systolic murmur, with a normal second heart sound.

Hb	90 g/l	Na ⁺	135 mmol/l	Bilirubin	5 µmol/l
Platelets	200 * 10 ⁹ /l	K ⁺	5.5 mmol/l	ALP	101 u/l
WBC	10 * 10 ⁹ /l	Urea	15 mmol/l	ALT	40 u/l
Neuts	8 * 10 ⁹ /l	Creatinine	230 µmol/l	corrected calcium	2.7 u/l
ESR	40 mm/hr				

What is the most likely diagnosis?

	Multiple myeloma
	Monoclonal gammopathy of undetermined significance
	Non-Hodgkin's, lymphoma
	Paget's disease
	Renal cell carcinoma with spinal metastases

□ Question 52 of 110

A 57 year old man presents to his General Practitioner with persistent headaches and blurred vision. The symptoms have been present over the past six months but have worsened in recent weeks. On close questioning, the patient also reported a feeling of general fatigue and intermittent muscle aches.

One year previously, the patient had been diagnosed with obstructive sleep apnoea secondary to morbid obesity and had been provided with non-invasive ventilation to use at night. However, the patient admitted that he rarely used this equipment due to a dislike for the tight face mask. Despite dietary and lifestyle advice the patient had gained 6 kg over the past year and had a BMI of 41 kg / m².

Neurological examination including fundoscopy was unremarkable. There were no tender or inflamed joints. Blood tests requested by the GP are detailed below.

Haemoglobin	19.5 g / dL
White cell count	7.5 * 10 ⁹ /l
Neutrophils	5.7 * 10 ⁹ /l
Lymphocytes	0.9 * 10 ⁹ /l
Platelets	195 * 10 ⁹ /l
Packed cell volume	0.60
Urea	5.9 mmol / L
Creatinine	110 µmol / L
Sodium	135 mmol / L
Potassium	4.1 mmol / L
eGFR	68 ml / min

Review of a full blood count performed 4 months previously was remarkable for previously unnoticed elevated PCV of 0.56. The patient was urgently referred to haematology for further management.

What is appropriate treatment for this patient's erythrocytosis?

	Aspirin
	Venesection
	Hydroxyurea
	Improved compliance with nocturnal non-invasive ventilation
	Referral to weight management service

□ Question 53 of 110

You are called to see a 55-year-old gentleman who is having a blood transfusion for symptomatic anaemia secondary to colon cancer. The nurses have been doing regular observations as documented below.

10am: Baseline observations prior to blood transfusion

Respiratory rate 20 breaths/min

Saturations 96% on air

Temperature 37.5 °c

Blood pressure 145/78 mmHg

Heart rate 74 beats/min

10:15 am: repeat observations after 15 mins of transfusion

Respiratory rate 19 breaths/min

Saturations 97% on air

Temperature 38.2 °c

Blood pressure 150/80 mmHg

Heart rate 72 beats/min

The nurses have already stopped the blood transfusion by the time you arrive to see the patient. On questioning the patient he feels well with no complaints of pain, itch or rashes. On examination his heart sounds are pure and chest is clear. He has no previous documented reactions to blood transfusions although the patient informs you he is allergic to penicillin. What instructions do you give the nurses?

	Take blood cultures and commence antibiotics
	Dispose of the remaining blood in the bag
	Restart the blood transfusion after giving the patient paracetamol
	Take blood cultures, repeat chest x ray and perform urinalysis
	Restart the blood transfusion an hour after giving the patient paracetamol

□ Question 55 of 110

□ □

A 55-year-old lady is seen in the Emergency Department with haematemesis. She developed upper abdominal pain yesterday and began vomiting dark brown material about an hour ago. She has also passed some loose stools today. She recalls having a couple of similar episodes of abdominal pain over the last 2 months but much less severe and not associated with vomiting.

Her past medical history includes hypertension, high cholesterol, type 2 diabetes, atrial fibrillation and chronic back pain. Her medications are bisoprolol, ramipril, atorvastatin, metformin, sitagliptin, apixaban, paracetamol and codeine. She also admits to taking some other over-the-counter pain relief for her back in recent months. She took her regular morning medication 10 hours ago but has not had any since.

On examination her heart rate is 105 beats per minute and blood pressure is 112/88 mmHg. She looks clammy and pale. She is very tender in the epigastric region with guarding and normal bowel sounds. There is malena on rectal examination.

Bloods have been sent but are not yet available, though a haemoglobin on venous gas is 96 g/l.

She is started on fluids and an urgent endoscopy is requested. Which medication should be given to help control the bleeding?

	Activated charcoal and prothrombin complex concentrate
	Activated charcoal and tranexamic acid
	Prothrombin complex concentrate and tranexamic acid
	Vitamin K and prothrombin complex concentrate
	Vitamin K and fresh frozen plasma

Overall score: **0%**

□ Question 58 of 110

A 37-year-old woman was admitted to the Intensive Care Unit (ICU) two days following chemotherapy. She had received her third of six cycles of chemotherapy for malignant ovarian cancer and without initial complication and was discharged the same day. Two days later she felt unwell and developed a fever. After liaising with the oncology unit she was admitted directly to the Medical Admission Unit. A full septic screen was conducted and she was treated empirically for neutropaenic sepsis with intravenous tazocin and gentamicin. Other than malignant ovarian cancer her past medical history was unremarkable, and there was no known metastasis. She was not taking any other drug therapy and was a non smoker. She did not consume alcohol.

Unfortunately whilst on the Medical Admission Unit she continued to deteriorate, developing fluctuating hemiparesis of initially the left lower limb, and then the right upper limb. Her level of consciousness dropped and her speech had become slurred. An urgent transoesophageal echocardiogram and CT head scan was conducted, pending availability of a MRI scan. She was promptly transferred to the Intensive Care Unit.

Upon arrival at the ICU she appeared very unwell, with a GCS of 12/15. Her blood pressure was 188/96 mmHg, her heart rate was 112, her respiratory rate was 22/min and her temperature was 38.5 degrees celsius. Examination of the cardiovascular system revealed the presence of normal heart sounds, a JVP of 3cm and warm well perfused peripheries. Examination of the respiratory system revealed good air entry in both lungs, with an oxygen saturation of 95% on air. Examination of her gastrointestinal system was unremarkable. Examination of her neurological system revealed localization to pain stimulus, with confusion and eye opening only in response to verbal prompting. Her speech was slurred. There was no other apparent focal neurological deficit, with otherwise normal cranial nerve and peripheral nervous system testing.

The results of the investigations conducted are as follows:

Hb	89g/l
Platelets	$38 \times 10^9/l$
WBC	$15.2 \times 10^9/l$
Reticulocyte count	4% (ie above normal range)
Blood film	presence of schistocytes, normocytic normochromic anaemia

Na ⁺	136 mmol/l
K ⁺	6.1 mmol/l
Urea	10.1 mmol/l
Creatinine	154 µmol/l

CRP	22 mg/l
ESR	45 mm/hr
Protein	78 g/l
Albumin	36 g/l
Adj calcium	2.42 mmol/l
Phosphate	0.95 mmol/l
Bilirubin	44 µmol/l
ALT	39 u/l
LDH	1286 u/l
ALP	102 u/l
PTT	14s
APTT	44s
INR	1.1
D-dimer	136 ng/ml

Chest x-ray: normal heart and lung appearances

ECG: heart rate 107bpm normal sinus rhythm, normal QRS and QTc intervals

Urinalysis: proteinuria ++, haematuria +, leuc/nit/glu negative

Blood MCS x3: pending result

Urine MCS: pending result

CT head: no space occupying lesion, mass shift or intracerebral haemorrhage seen

Transoesophageal echocardiogram: normal systolic function, normal appearance of all valves, no evidence of vegetation seen

In the context of the likely underlying diagnosis, what is the best immediate management step?

	Commence immediate plasma exchange
	Commence high dose intravenous hydrocortisone
	Commence platelet infusion
	Commence IV meropenem and IV antifungal therapy

□ Question 58 of 110

A 37-year-old woman was admitted to the Intensive Care Unit (ICU) two days following chemotherapy. She had received her third of six cycles of chemotherapy for malignant ovarian cancer and without initial complication and was discharged the same day. Two days later she felt unwell and developed a fever. After liaising with the oncology unit she was admitted directly to the Medical Admission Unit. A full septic screen was conducted and she was treated empirically for neutropaenic sepsis with intravenous tazocin and gentamicin. Other than malignant ovarian cancer her past medical history was unremarkable, and there was no known metastasis. She was not taking any other drug therapy and was a non smoker. She did not consume alcohol.

Unfortunately whilst on the Medical Admission Unit she continued to deteriorate, developing fluctuating hemiparesis of initially the left lower limb, and then the right upper limb. Her level of consciousness dropped and her speech had become slurred. An urgent transoesophageal echocardiogram and CT head scan was conducted, pending availability of a MRI scan. She was promptly transferred to the Intensive Care Unit.

Upon arrival at the ICU she appeared very unwell, with a GCS of 12/15. Her blood pressure was 188/96 mmHg, her heart rate was 112, her respiratory rate was 22/min and her temperature was 38.5 degrees celsius. Examination of the cardiovascular system revealed the presence of normal heart sounds, a JVP of 3cm and warm well perfused peripheries. Examination of the respiratory system revealed good air entry in both lungs, with an oxygen saturation of 95% on air. Examination of her gastrointestinal system was unremarkable. Examination of her neurological system revealed localization to pain stimulus, with confusion and eye opening only in response to verbal prompting. Her speech was slurred. There was no other apparent focal neurological deficit, with otherwise normal cranial nerve and peripheral nervous system testing.

The results of the investigations conducted are as follows:

Hb	89g/l

□ Question 59 of 110

You are seeing a 35 year old gentleman in outpatient renal clinic with known CKD5 (chronic kidney disease stage 5) as a consequence of analgesic induced nephropathy. He tells you that over the past few weeks he has been feeling increasingly tired and has noticed that he's been having headaches. Asking more about his tiredness he states that he can get around his house, but has noticed increased shortness of breath when climbing the stairs. On examination it is clear that he has pale mucous membranes and a slightly hyperdynamic circulation.

Bloods taken from the morning are as follows:

Hb	82 g/l
Platelets	154 * 10 ⁹ /l
WBC	2.7 * 10 ⁹ /l
Bilirubin	14 µmol/l
ALP	154 u/l
ALT	7 u/l
Albumin	28 g/l
Ferritin	350 ng/ml
Transferrin saturations	24%
B12	451 pg/ml
Folate	4.8 nmol/nl
TSH	2.1 mIU/L

How would you manage this patient's anaemia?

	Start ferrous fumarate 210mg three times daily
	Intravenous iron infusion guided by weight and Hb

	Start an ESA (erythrocyte colony stimulating agent)
	Transfuse 1 unit of packed red cells
	Transfuse 1 unit of packed red cells then start an ESA (erythrocyte colony stimulating agent)

□ Question 60 of 110

□ □

A 77-year-old lady was seen in the haematology outpatient clinic for her monthly follow-up. She has been seen in the haematology clinic for the last six months having been referred by her GP following an anomaly on her blood investigations. Overall she has been feeling well though for the last three weeks she has been feeling increasingly tired. She has noted that her appetite has been reduced for the last three months though she has not lost any weight during this time. In spite of the tiredness she is still able to lead an active life, regularly enjoying long distance rambling and gardening. She denied the presence of other symptoms, including the absence of fever or night sweats. She has a past medical history comprising asthma, hypertension, type 2 diabetes mellitus and hypercholesterolaemia for which she has been prescribed felodipine 5mg M/R OD, atorvastatin 20mg ON, Clenil modulite 2 puffs BD and metformin 500mg TDS.

Examination revealed the presence of a well elderly lady who was independently mobile. Her blood pressure was 122/82 mmHg, heart rate 82bpm and temperature 36.9 Celsius. Examination of her cardiovascular and respiratory systems revealed the presence of normal heart and breath sounds and a JVP of 3cm. Examination of her gastrointestinal and lymphatic systems revealed the presence of a smooth edge 2 fingerbreadth below the left subcostal margin and bilateral small cervical lymphadenopathy, with the maximum node size less than 1cm.

Investigations reveal the following:

Results from clinic three months ago:

Hb	112 g/l
Platelets	$242 \times 10^9/l$
WBC	$22.6 \times 10^9/l$
Neutrophils	$2.1 \times 10^9/l$
Lymphocytes	$19.9 \times 10^9/l$
Eosinophils	$0.4 \times 10^9/l$
Monocytes	$0.2 \times 10^9/l$

Renal and liver function tests were normal.

Blood film: lymphocytosis with atypical lymphocytes

Bone marrow aspirate: infiltration with 25% lymphocytes
Peripheral blood flow cytometry: presence of circulating clonal B-lymphocytes expressing CD5, CD19, CD20, CD 23, and an absence of FMC-7 staining

Results from clinic on this occasion:

Hb	106 g/l
Platelets	162 * 10 ⁹ /l
WBC	34.2 * 10 ⁹ /l
Neutrophils	2.3 * 10 ⁹ /l
Lymphocytes	31.5 * 10 ⁹ /l
Eosinophils	0.3 * 10 ⁹ /l
Monocytes	0.1 * 10 ⁹ /l

What is the single next best step management step?

	Commence prednisolone therapy
	Commence chlorambucil therapy
	Commence fludarabine therapy
	Commence rituximab therapy
	Observe in clinic and repeat tests in one month

□ Question 62 of 110

A 33 year female of Arabic descent with bullous pemphigus is admitted electively for intravenous immunoglobulins. She has no other past medical history, no recent travel history and has lived in rural Norfolk her whole life. On day 4 of a 5 day planned course of treatment, she develops pyrexia, nausea and vomiting. On examination, you note mild neck stiffness and photophobia. She also complains of a posterior headache. Her serum markers are as below:

WBC	14.0 * 10 ⁹ /l
Neuts	11.0 * 10 ⁹ /l

Na ⁺	133 mmol/l
K ⁺	3.8 mmol/l
Urea	4.7 mmol/l
Creatinine	80 µmol/l
CRP	4 mg/l

A CT head is unremarkable. The immunoglobulin is stopped. You perform a lumbar puncture: WCC 10/mm³, protein 0.4g/L, no organisms, opening pressure 17.8 cm H₂O. Blood cultures taken during a temperature spike grow no organisms after 48 hours. What is the diagnosis?

	Aseptic meningitis
	Bullous pemphigus flare
	TB reactivation, resulting in TB meningitis
	Viral meningitis
	Bacterial meningitis

Overall score: **0%**

□ Question 63 of 110

A 52 year old female with known advanced breast carcinoma presents with a three week history of increased abdominal and lower limb swelling. She denies any shortness of breath or chest pain. She is currently undergoing third line palliative chemotherapy and on her last staging CT scan, she has stable disease but with metastases to her lungs, livers, multiple lymph nodes and right sacrum. She has not changed her medications recently. On examination, her cardiovascular and chest examination are unremarkable. You note sacral oedema and pitting oedema on both legs to thighs. Her abdomen is grossly distended and the patient informs you that this has gradually increased over the past month. JVP is not visualised. She is warm and well perfused peripherally. There is mild shifting dullness and areas of resonance, bowel sounds are present. Her blood test demonstrate:

Hb	10.8 g/dl
Platelets	$212 \times 10^9/l$
WBC	$7.8 \times 10^9/l$
INR	1.6

Bilirubin	40 $\mu\text{mol/l}$
ALP	60 u/l
ALT	380 u/l
Albumin	39 g/l

Which investigation is most likely to reveal the cause of this deterioration?

	CT chest, abdomen, pelvis with contrast
	CT venogram
	Ultrasound abdomen
	Echocardiogram

	Ascitic tap (diagnostic)

Question 64 of 110

□ □

A 27 year old woman presents to the Emergency Department with a sudden onset of swelling of the hands and face. She describes multiple similar episodes over the past few years, but this episode is the most severe. She cannot recall any obvious precipitant. On previous occasions the symptoms have subsided within thirty minutes but on this occasion they have worsened over the course of an hour. On examination, there is significant swelling of the lips which are dry and shiny. The tongue is not enlarged. There is no stridor and the chest is clear. Respiratory rate is 22 and oxygen saturations are 96% on air. The hands are swollen and slightly erythematous but there is no pain or itching and no lymphadenopathy. Heart rate is 106bpm and blood pressure is 118/79mmHg. Tympanic temperature is 36.7°C. A diagnosis of hereditary angioedema is suspected.

Which one of the following is not implicated in the pathogenesis of hereditary angioedema?

	C1-esterase inhibitor
	Bradykinin
	Histamine
	Kallikrein
	High molecular weight kininogen

□ Question 66 of 110

A 35-year-old patient with known sickle cell disease presents to the emergency department with new onset of left arm and facial weakness. The symptoms began earlier in the day. He is normally very careful with his sickle disease and ensures he is well hydrated and avoids the cold. His wife admits that over the last few days he has been suffering from nausea and vomiting and diarrhoea after he had a takeaway meal 3 days ago, On examination he his observations are within normal parameters. He has slurred speech and an obvious left facial droop with forehead sparing. He has power of 0/5 in his left arm but is otherwise neurologically intact.

His blood test show:

Hb	100 g/l
Platelets	330 * 10 ⁹ /l
WBC	8.9 * 10 ⁹ /l
INR	1.0

Na ⁺	138 mmol/l
K ⁺	3.5 mmol/l
Urea	9.9 mmol/l
Creatinine	135 µmol/l
CRP	19 mg/L(<10)

Bilirubin	12 µmol/l
ALP	89 u/l
ALT	39 u/l
Albumin	39 g/l

He is seen by the stroke team who arrange an urgent CT head which is reported as normal. What is the appropriate

treatment for this gentleman?

	Thrombolysis
	Aspirin
	Plasmapheresis
	Methylprednisolone
	Exchange transfusion

Question 68 of 110

A 60-year-old female patient is receiving etanercept for long term rheumatoid arthritis. She attends the general medical clinic with increasing shortness of breath on exertion. She has received treatment for arthritis for many years and has in the past received methotrexate. This was stopped due recurrent infections. She has had no recent courses of steroids. Her symptoms of arthritis are well controlled on her current treatment regimen.

On examination the patient had a blunted affect. Her tongue appeared mildly swollen and red with some area of soreness at the corners of her mouth. She did not exhibit finger clubbing but the nails appeared brittle. Her pulse was 92 bpm and her blood pressure 106/68 mmHg. Examination of her cardiorespiratory system revealed normal heart sounds with no added sounds and the occasional fine crepitation in her lung fields.

Basic investigations such as blood tests and a chest x-ray were undertaken. Results are shown below.

Hb	8.2 g/dl
MCV	109fl
Haematocrit	0.39
Platelets	$380 \times 10^9/l$
WBC	$9.4 \times 10^9/l$

Renal function	normal
Liver function	normal

CXR	normal
-----	--------

	Pernicious anaemia
	Sideroblastic anaemia

	Anaemia of chronic disease
	Iron deficiency anaemia
	Aplastic anaemia

□ Question 69 of 110

A 70-year-old man is admitted to hospital with shortness of breath and a productive cough. Following initial investigation a community-acquired pneumonia is diagnosed and treatment with IV fluids and IV antibiotics initiated promptly. Subcutaneous enoxaparin for venous thromboprophylaxis was initiated on the day of admission. Due to persistent hypotension and oliguria secondary due to presumed septic shock, the patient was admitted to the General Intensive Care Unit for inotropic support around 12 hours after initial presentation.

The patient's past medical history featured a previous ST elevation myocardial infarction, treated with primary percutaneous coronary interventions one year previously. Regular medications included Aspirin, Clopidogrel, Ramipril, Bisoprolol and Atorvastatin. The patient had no known drug allergies and lived independently in a house with his wife.

With the above management, the patient's condition stabilised and he was discharged to a respiratory ward on day 3 of the admission. Routine blood tests taken on day 7 of admission demonstrated a marked fall in platelet count compared to admission bloods. Full examination of the patient at this time did not demonstrate any evidence of venous thrombosis with no skin changes. Following advice from haematology further investigations were requested as detailed below.

Blood results	Day 0 (admission)	Day 3	Day 7
Platelets ($\times 10^9$ / microlitre)	189	156	87
International normalised ratio	1.1	1.3	1.2

Heparin induced thrombocytopenia antibodies: positive (moderate titre)

What further investigation is required (if any) to confirm a diagnosis of heparin induced thrombocytopenia?

	Serotonin release assay
	Repeat heparin induced thrombocytopenia antibodies
	Venous doppler ultrasound of lower limbs
	Fibrinogen break-down products

No further investigation required

□ Question 70 of 110

□ □

A 77-year-old man with known atrial fibrillation is admitted following an upper gastrointestinal haemorrhage. His atrial fibrillation is managed using bisoprolol and warfarin. Since his admission, he has had four large episodes of haematemesis. You, the emergency department doctor, request the patient's INR to be checked as one of a series of investigations. The haematology laboratory phone through and inform you his INR is 8.5. He is currently hypotensive (90/45 mmHg) and tachycardic (120 beats per minute). You begin resuscitation using 0.9% saline, and send a cross match, group and save. What is the most appropriate treatment of this patient's INR?

	Fresh frozen plasma + stop warfarin
	Vitamin K + stop warfarin
	Prothrombin complex concentrates
	Prothrombin complex concentrates + vitamin K + stop warfarin
	Stop warfarin

Question 71 of 110

□ □

A 30-year-old woman presents to the emergency department with severe, progressive abdominal pain over the past day. The pain is accompanied by nausea, vomiting and diarrhoea. The patient recalls similar episodes in the past that progressed over a few days and lasted for a week. Temperature is 37°C, blood pressure is 140/100 mmHg, pulse is 120/min and respirations are 16/min.

On examination: minimal abdominal tenderness and rebound tenderness. She has a history of abdominal surgery for suspected appendicitis and biliary disease, neither of which was confirmed once inside the abdomen.

Which of the following will help to confirm the diagnosis?

	Erythrocyte porphyrins
	Faecal porphyrins
	Plasma porphyrins
	Urine porphobilinogen
	Urine porphyrins

□ Question 74 of 110

A 32 year old male presents with a progressive worsening non-specific lethargy. 9 months ago, he had returned from an active holiday from New Zealand and now feels lethargic to the point that he can no longer work in his job as a computer programmer. In this period, he has been treated for two deep vein thromboses with low molecular heparin, the first initially attributed to his return flight from New Zealand. He reports three episodes of rose coloured urine over the past 4 months and intermittent episodes of abdominal cramps that his GP had diagnosed to be irritable bowel syndrome.

On examination, you note mild conjunctival pallor and jaundiced sclera. Respiratory, cardiovascular and abdominal examinations are unremarkable. His blood results are as follows:

Hb	7.6 g/dl
fl	
MCV	92 fl
Platelets	$276 \times 10^9/l$
WBC	$4.1 \times 10^9/l$
Reticulocytes	18%
Haptoglobin	2 (normal range 41-165 mg/dL)
LDH	2128 (normal range 140-280 units/L)
Coombs' test	negative at 4 and 37 degrees

What is the definitive treatment for the underlying condition?

	Packed red blood cell transfusion
	Anti-retroviral treatment
	Bone marrow transplant
	R-CHOP chemotherapy

	Intravenous iron replacement

Dashboard

□ Question 75 of 110

A 50-year-old gentleman presented with a 3 day history of left leg swelling and pain. He denied any chest pain or breathlessness. His past medical history included ischaemic heart disease, diabetes and hypertension. He maintains an active lifestyle and he had no risk factors for venous thromboembolism. He is an ex-smoker (20 pack year history).

On examination his heart sounds were normal, chest was clear and abdomen was soft and non-tender. His vitals include heart rate = 70 beats per minute, blood pressure = 140/70 mmHg, SaO₂ = 99% on air, T = 36.6°C and respiratory rate = 16 breaths per minute. His chest X-ray was normal, ECG revealed sinus rhythm and urine was clear. The following blood tests have been obtained:

Hb	10.5 g/dl
Platelets	250 * 10 ⁹ /l
WBC	10.4 * 10 ⁹ /l
D-dimer	Positive

Na ⁺	133 mmol/l
K ⁺	4.6 mmol/l
Urea	7.2 mmol/l
Creatinine	101 µmol/l
CRP	10 mg/l

Bilirubin	12 µmol/l
ALP	140 u/l
ALT	30 u/l
Corrected Ca ²⁺	2.60 mmol/l

Albumin	35 g/l
---------	--------

Ultrasound of the left leg revealed an extensive thrombus.

What is the next best investigation?

	Computed tomography of abdomen / pelvis
	Echocardiogram
	Computed tomography pulmonary angiography
	Thrombophilia screen
	V/Q scan

□ Question 76 of 110

A 62 year old man is attending his GP as part of regular screening. He has a past medical history significant only for hypertension for which he has been taking amlodipine for many years. He reports no specific symptoms of note and is still working full time as an accountant. His blood pressure on this visit is 132/78mmHg and his urinalysis shows no abnormalities. Blood tests were taken for routine monitoring.

Hb	13.8 g/dl
Platelets	$362 \times 10^9/l$
WBC	$6.3 \times 10^9/l$

Na ⁺	142 mmol/l
K ⁺	4.2 mmol/l
Urea	4.6 mmol/l
Creatinine	84 μ mol/l

Adjusted calcium	2.41mmol/l
Lactate Dehydrogenase	300 IU/l
Albumin	36 g/l
Globulin	52 g/l

An abnormal protein band is detected during analysis and the GP arranges for further review with the Haematologist at the hospital. Further investigations are undertaken:

Monoclonal paraprotein 18g/l

Bone Marrow examination showing 6% plasma cells

Skeletal Survey showing no abnormalities

What is the diagnosis?

	Multiple Myeloma
	Hodgkins Lymphoma
	Waldenström's macroglobulinemia (lymphoplasmacytic lymphoma)
	Asymptomatic Myleoma
	Monoclonal gammopathy on uncertain significance (MGUS)

□ Question 77 of 110

A 30-year-old woman is referred to haematology clinic by her GP for assessment for possible hereditary haemochromatosis. The patient reports that her 37-year-old brother has recently been diagnosed with the condition after developing progressive fatigue and joint pains over the previous few months. The patient is very concerned that she too may have inherited the condition, especially as at the time of his diagnosis her brother has been found to have significant damage to his liver and diabetes secondary to iron overload. With her brother's consent, the patient had brought a copy of his medical records to the clinic appointment and details of his investigations are given below.

Aside from the anxiety induced by her brother's recent illness, the patient reported being in generally good health. She reported leading a busy life, working full time as a primary school teacher in addition to raising her 4-year-old daughter. In the context of these commitments and activities, the patient did not feel she was unreasonably tired or lethargic and did not experience significant joint pains.

The patient had a history of psoriasis that was well controlled with topical treatments. The pregnancy and delivery of her daughter had been uncomplicated. The patient reported a tendency to a heavy menstrual flow and had previously been prescribed tranexamic acid for this by her GP although she had not found significant benefit from this treatment. Aside from topical treatments for her psoriasis, the patient took no regular, prescribed medications and had no known allergies to medications.

Physical examination of the patient was unremarkable; in particular, no signs of chronic liver disease were identified on gastrointestinal system examination.

A summary of the patient's brother's investigations for hereditary haemochromatosis at the time of his diagnosis is given below.

Ferritin	1,527 microgram / L (30-300)
Transferrin saturation	78 % (15-45)
HFE gene analysis	homozygous for C282Y mutation
HbA1C	53 mmol / mol (reference < 42)
Liver magnetic resonance imaging	Generalised cirrhosis; low signal seen on all sequences, especially T2 weighted

The patient had undergone basic blood tests arranged by her GP at the time of referral, with results given below.

Haemoglobin	136 g / dL
Mean cell volume	84.1 fl
Ferritin	190 microgram / L (30-300)
Transferrin saturation	43 % / (15-45)

What is the appropriate next investigation to confirm or exclude the patient suffering from hereditary haemochromatosis?

	Pituitary hormone panel
	HFE gene analysis
	Liver magnetic resonance imaging (T2 weighted)
	Patient asymptomatic and normal iron studies, no further investigations indicated
	Liver biopsy

Dashboard

Overall score: 0%

□ Question 79 of 110

A 62 year old man had a routine set of blood tests performed by his General Practitioner. These demonstrated an erythrocytosis (Packed Cell Volume 0.56) but no other abnormality. Further questioning by the GP found that the patient had no symptoms of hyperviscosity, was a non-smoker with no symptoms of daytime somnolence and took no regular medications. Past medical history included only a left knee hemiarthroplasty performed due to osteoarthritis.

Two weeks after the initial blood test, the patient's bloods were repeated and showed a persistence of the erythrocytosis. A referral to haematology clinic was made for further investigation. Details of further investigations arranged through haematology clinic are listed below.

Haemoglobin	18.8 g / dL
White cell count	$6.7 \times 10^9/\text{L}$
Neutrophils	$3.2 \times 10^9/\text{L}$
Lymphocytes	$2.1 \times 10^9/\text{L}$
Monocytes	$0.8 \times 10^9/\text{L}$
Eosinophils	$0.3 \times 10^9/\text{L}$
Basophils	$0.3 \times 10^9/\text{L}$
Platelets	$202 \times 10^9/\text{L}$
Packed cell volume	0.59
Urea	4.5 mmol / L
Creatinine	97 micromol / L
Sodium	140 mmol / L
Potassium	3.9 mmol / L
eGFR	85 ml / min
Ferritin	80 ng / ml

Albumin	38 g / L
Alkaline phosphatase	89 U / L
ALT	25 U / L
Bilirubin	20 micromol / L
JAK 2 V617F mutation	Negative
Serum erythropoietin	0 U / L (reference 0-19)

Blood film: no abnormality detected; no features of myeloproliferative disease

Abdominal ultrasound: liver, hepatic duct system and gallbladder unremarkable; mild-moderate splenomegaly; kidneys and renal tract unremarkable

What is the most appropriate next investigation?

<input type="checkbox"/>	JAK2 exon 12 mutation testing

□ Question 79 of 110

A 62 year old man had a routine set of blood tests performed by his General Practitioner. These demonstrated an erythrocytosis (Packed Cell Volume 0.56) but no other abnormality. Further questioning by the GP found that the patient had no symptoms of hyperviscosity, was a non-smoker with no symptoms of daytime somnolence and took no regular medications. Past medical history included only a left knee hemiarthroplasty performed due to osteoarthritis.

Two weeks after the initial blood test, the patient's bloods were repeated and showed a persistence of the erythrocytosis. A referral to haematology clinic was made for further investigation. Details of further investigations arranged through haematology clinic are listed below.

Haemoglobin	18.8 g / dL
White cell count	$6.7 \times 10^9/\text{L}$
Neutrophils	$3.2 \times 10^9/\text{L}$
Lymphocytes	$2.1 \times 10^9/\text{L}$
Monocytes	$0.8 \times 10^9/\text{L}$
Eosinophils	$0.3 \times 10^9/\text{L}$
Basophils	$0.3 \times 10^9/\text{L}$
Platelets	$202 \times 10^9/\text{L}$
Packed cell volume	0.59
Urea	4.5 mmol / L
Creatinine	97 micromol / L
Sodium	140 mmol / L
Potassium	3.9 mmol / L
eGFR	85 ml / min
Ferritin	80 ng / ml

Albumin	38 g / L
Alkaline phosphatase	89 U / L
ALT	25 U / L
Bilirubin	20 micromol / L
JAK 2 V617F mutation	Negative
Serum erythropoietin	0 U / L (reference 0-19)

Blood film: no abnormality detected; no features of myeloproliferative disease

Abdominal ultrasound: liver, hepatic duct system and gallbladder unremarkable; mild-moderate splenomegaly; kidneys and renal tract unremarkable

What is the most appropriate next investigation?

	JAK2 exon 12 mutation testing
	Bone marrow aspiration and trephine biopsy
	Measurement of red cell mass
	CT brain
	Erythropoietin receptor gene analysis

Question 80 of 110

A 23 year old female has presented with her first episode of seizure on the labour ward, 2 days after delivering her first child by normal vaginal delivery. She reports a fluctuating generalised headache over the past 3 months but had not previously sought medical attention. In addition, she had spiked 2 fevers over 38°C over the past 48 hours, with no dysuria, diarrhoea or vomiting, productive cough or signs of meningism. She has no past medical history, is a life-long non-smoker and has been abstinent of alcohol for 9 months, previously drinking 4 units per week. Her seizure was witnessed and described as tonic-clonic jerking of all 4 limbs, associated with loss of consciousness, terminated after 4mg of intravenous lorazepam after 4 minutes. On examination, she appears post-ictal but responding to voice despite being sleepy. Pupils are reactive and equal. Plantars are downgoing bilaterally. Cardiovascular, abdominal and respiratory examinations are unremarkable. No skin rashes, neck stiffness or photophobia are noted. Her blood results are as follows:

Hb	7.5 g/dl
MCV	87 fl
Platelets	23 * 10 ⁹ /l
WBC	9.2 * 10 ⁹ /l
Blood film	schistocytes
Coomb's test	negative
CRP	30 mg/l
Urea	12.6mmol/l
Creatinine	154 µmol/l
Bilirubin	28 µmol/l
ALP	98 u/l
ALT	28 u/l
γGT	23 u/l

A CT head with contrast demonstrated no areas of ischaemia, haemorrhage or space occupying lesion.

Which is the next most appropriate immediate management?

	Plasma exchange
	Intravenous 3rd generation cephalosporin antibiotics
	Intravenous phenytoin loading
	MRI head with contrast
	Intravenous steroids

□ Question 81 of 110

An 16 year-old presents with a 2 day history of abdominal pain. On questioning, this is a constant ache with no obvious exacerbating or precipitating factors. He is opening his bowels as normal. He is usually well, aside from a cold in the preceding week.

He has an antalgic gait and complains of pain in his left knee. Examination of his left knee is unremarkable. He has bilateral mild periorbital oedema. There is also an extensive purpuric rash, focused around his buttocks and posterior leg. This is non-blanching.

Urinalysis: Blood 3+, Protein 2+

Hb	135 g/l	Na ⁺	135 mmol/l
Platelets	230 * 10 ⁹ /l	K ⁺	3.5 mmol/l
WBC	11 * 10 ⁹ /l	Urea	7 mmol/l
Neuts	9 * 10 ⁹ /l	Creatinine	85 µmol/l

What is the most likely diagnosis?

	Intussusception
	Henoch-Schonlein purpura
	Idiopathic thrombocytopenic purpura
	Glomerulonephritis
	Bacterial meningitis

Overall score: **0%**

□ Question 82 of 110

A 52-year-old male was seen in the rapid access Transient Ischaemic Attack (TIA) clinic. He presented to his GP with new onset left leg and arm weakness three days ago. The weakness lasted for 90 minutes and fully resolved with no residual defect. He had a past medical history of hypertension, obstructive sleep apnoea and a left sided deep vein thrombosis eight years ago. His medication comprised ramipril 5mg OD. He smoked ten cigarettes per day and did not drink alcohol.

On examination, he had obvious truncal obesity and a flushed complexion. Blood pressure was 128/82 mmHg, heart rate 78/min, respiratory rate 16/min and oxygen saturations 99% on air. Cardiovascular examination revealed a regular pulse and nil else of note. Respiratory and gastrointestinal examination were normal, though examination of the abdomen was somewhat limited by the presence of truncal obesity. Neurological examination was unremarkable with normal cranial nerve, fundoscopy and peripheral neurological examinations.

Initial investigations revealed the following results:

Hb	191 g/l
MCV	98 fl
Hct	0.523
Platelets	$502 \times 10^9/l$
WBC	$14.0 \times 10^9/l$
Neutrophils	86%
Lymphocytes	10%
Monocytes	4%

HbA1c	43 mmol/mol
Fasting cholesterol	5.6 mmol/l

ECG: 76bpm normal sinus rhythm no other abnormality

Chest x-ray: unremarkable
24 hr ECG: no arrhythmia seen
Echo: normal systolic function, mild aortic stenosis with pressure gradient of 42mmHg
CT head: normal intracranial appearances, no evidence of mass shift, space occupying lesion or haemorrhage

What is the most appropriate next investigation most likely to lead to the underlying diagnosis?

	Cardiac catheterization
	Testing for presence of JAK2 mutation
	Bone marrow biopsy
	Radioisotope scanning of circulating blood volumes
	MRI scanning of the abdomen

□ Question 86 of 110

An 83 year old female presents with increased right calf swelling, erythema and tenderness four days after an initial admission for community acquired pneumonia. Her past medical history includes hypertension, type 2 diabetes mellitus and a previous right total knee replacement 10 years ago. She is currently on oral antibiotics and an ultrasound Doppler demonstrates a right calf deep vein thrombus. She is subsequently started on low molecular weight heparin for 6 months as per guidelines for a provoked deep vein thrombosis.

Three days afterwards, an increase in ALT and GGT prompts a CT abdomen, demonstrating an ischaemic injury to the liver on triple phase imaging. A further two days after her DVT, the patient awaits admission to a rehabilitation ward prior to her discharge back to her own home. Her blood tests are as follows:

Hb	11.1 g/dl
MCV	87 fl
Platelets	$28 \times 10^9/l$
WBC	$13.2 (21) \times 10^9/l$
Neuts	$11.2 (17) \times 10^9/l$
INR	1.1
APTT	95s
CRP	30 (185) mg/l

What is the optimal management?

	Stop low molecular weight heparin
	Stop low molecular weight heparin, start dabigatran
	Stop low molecular weight heparin, start warfarin

	Continue low molecular heparin
	One pool platelet transfusion

Dashboard

Overall score: **0%**

□ Question 88 of 110

A 65-year-old man is seen in the haematology clinic for review of test results. He has been fatigued for the last three months and has experienced night sweats. On examination he is pale with a palpable spleen 4cm below the costal margin, mildly tender on palpation. His only other past medical history is of osteoarthritis.

His results are as follows:

Hb	89 g/l	Na ⁺	140 mmol/l
Platelets	205 * 10 ⁹ /l	K ⁺	4.0 mmol/l
WBC	5 * 10 ⁹ /l	Urea	5.8 mmol/l
Neuts	3.6 * 10 ⁹ /l	Creatinine	72 µmol/l
Lymphs	1.2 * 10 ⁹ /l	CRP	3 mg/l

Blood film: Anisocytosis with mild hypochromia. Tear drop cells.

CT chest/abdomen/pelvis: Splenic enlargement. No suspicious mass lesions seen. 1cm simple right renal cyst. No lymphadenopathy.

Bone marrow biopsy: Fibrosis

Which initial therapy should be used to treat this gentleman?

	Chlorambucil
	Fludarabine
	Hydroxycarbamide
	Interferon alpha
	Lenalidomide

Question 90 of 110

A 50 year old woman was referred to haematology clinic for management of a persistent erythrocytosis that had been monitored by her General Practitioner over the previous 6 months. The patient was asymptomatic and in particular reported no headaches or visual changes. Past medical history was remarkable only for internal fixation of a tibial fracture sustained in a car accident 5 years previously. There is no strong family history of venous thrombosis or ischaemic heart disease. The patient took no regular medications and worked as an accountant. She is a life-long non-smoker and drinks approximately 10 units of alcohol per week.

Following assessment at haematology, further investigations were requested as listed below.

Hb	# g/dl
Platelets	# * 10 ⁹ /l
WBC	# * 10 ⁹ /l

Haemoglobin	18.7 g / dL
White cell count	6.1 * 10 ⁹ /l
Neutrophils	3.5 * 10 ⁹ /l
Lymphocytes	1.0 * 10 ⁹ /l
Monocytes	0.7 * 10 ⁹ /l
Eosinophils	0.4 * 10 ⁹ /l
Basophils	0.5 * 10 ⁹ /l
Platelets	276 * 10 ⁹ /l
Packed cell volume	0.57
Urea	4.5 mmol / L
Creatinine	95 micromol / L
Sodium	142 mmol / L

Potassium	4.5 mmol / L
Ferritin	56 ng / mL
Albumin	35 g / L
Alkaline phosphatase	80 U / L
ALT	20 U / L
Bilirubin	18 micromol / L
JAK 2 V617F mutation	Positive
Serum erythropoietin	3 U / L (reference 0-19)

Blood film: no abnormality detected

Abdominal ultrasound: liver, hepatic duct system and gallbladder unremarkable; mild-moderate splenomegaly; kidneys and renal tract unremarkable

What is the appropriate management for the patient's erythrocytosis?

	Aspirin and venesection with target PCV < 0.45
	Aspirin and venesection with target PCV 0.45-0.50
	Aspirin
	Venesection with target PCV 0.45-0.50
	Hydroxyurea

Question 91 of 110

□ □

You receive a phone call requesting advice from a GP. A patient who is on long term warfarin for atrial fibrillation has been found to have an INR of 10.0 following a recent course of antibiotics. She is not bleeding and only has long standing senile purpura on her arms with no new bruising. What is the most appropriate advice to give?

	Admit for intravenous vitamin K and monitoring
	Give oral vitamin K and continue warfarin at usual dose
	Give oral vitamin K and stop warfarin until INR < 5
	Give oral vitamin K and stop warfarin until INR < 3
	Stop warfarin and restart when INR < 3

Question 92 of 110

□ □

A 72-year-old lady who has a background of multiple myeloma is being investigated for bilateral carpal tunnel syndrome, worsening shortness of breath and oedema. Her investigation results are as follows:

Hb	105 g/l
Platelets	$145 \times 10^9/l$
WBC	$7.2 \times 10^9/l$

Ca ⁺	2.70 mmol/l
Urea	4.3 mmol/l
Creatinine	150 μ mol/l

Urine protein >3.5/day

Chest x-ray shows cardiomegaly with fluid overload

What are her symptoms most likely to be due to?

	Membranous nephropathy
	Amyloidosis
	Heart failure
	Minimal change disease
	Treatment side effects

□ Question 93 of 110

□ □

A 61-year-old woman comes for review. Around one year ago she finished a 6 month course of warfarin after being diagnosed with an unprovoked, proximal deep vein thrombosis. For the past few weeks she has been experiencing 'heaviness' and 'aching' in the the same leg. This is associated with an itch and some swelling, although this seems to go down each night. Past medical history of note includes osteoarthritis and type 2 diabetes mellitus.

On examination prominent varicose veins are seen on the affected leg with some brown discolouration of the skin above the medial malleolus. There is no difference in the circumference of the calves. Her temperature is 36.9°C, pulse 78/min and blood pressure 108/82 mmHg. What is the most likely diagnosis?

	Recurrence of deep vein thrombosis
	Post-thrombotic syndrome
	Cellulitis
	Ruptured Baker's cyst
	Necrobiosis lipoidica

Dashboard

□ Question 99 of 110

A 47-year-old lady presented with shortness of breath and a nosebleed. She had been experiencing heavy nosebleeds over the past fifteen years and had twice required cauterization. On this admission she felt very tired, with shortness of breath and chest pain on minimal exertion.

Aside from nosebleeds she had a past medical history of hypertension and hypothyroidism. She had recently consulted a cosmetic surgeon privately as she had spider veins over her lips which she wished to have removed.

She lived with her husband who had been diagnosed with multiple sclerosis and her 18-year-old son who had learning difficulties and epilepsy. She reported that her mother and sister also experienced frequent nosebleeds.

On examination there was conjunctival pallor. The lung fields were clear on auscultation and both heart sounds were present with a systolic murmur audible over the aortic region. The abdomen was soft and non-tender with no palpable masses or organomegaly. On inspection of the skin there was a bruise in the left antecubital fossa and no rashes.

What is the most likely unifying diagnosis?

	Von Willebrand disease
	Wegeners granulomatosis
	Von Hippel Lindau disease
	Idiopathic Thrombocytopaenic Purpura
	Hereditary haemorrhagic telangiectasia

Dashboard

□ Question 100 of 110

□ □

A 28-year-old man is admitted to the Medical Admissions Unit with a 2-day history of itching, right upper quadrant pain, and abdominal distension. The pain started as a dull ache but became constant and severe over the course of several hours.

His past medical history is remarkable only for a left lower limb DVT diagnosed at age 20. He takes no regular medications and he is a non-smoker. He drinks 2-3 units of alcohol per week and denies intravenous drug use.

Examination reveals a jaundiced young man with pale conjunctivae. He appears deeply uncomfortable. His abdomen is moderately distended with marked right upper quadrant tenderness. His liver and spleen are both palpable 2cm below the costal margin. Shifting dullness is demonstrable on percussion of the abdomen.

His blood results are as follows:

Hb	101 g/l	Na ⁺	139 mmol/l	Bilirubin	109 µmol/l
MCV	102.4 fl	K ⁺	4.2 mmol/l	ALP	284 u/l
Platelets	63 * 10 ⁹ /l	Urea	6.7 mmol/l	ALT	684 u/l
WBC	12.9 * 10 ⁹ /l	Creatinine	108 µmol/l	γGT	179 u/l
Neuts	10.8 * 10 ⁹ /l			Albumin	27 g/l
Lymphs	0.9 * 10 ⁹ /l			LDH	759 u/l

His abdominal ultrasound scan is consistent with hepatic vein thrombosis and the patient is started on low molecular weight heparin. Following a review by the Haematologists, a diagnosis of paroxysmal nocturnal haemoglobinuria is made and the patient is advised to start treatment with eculizumab.

Given the proposed treatment strategy, which of the following vaccinations should the patient be offered?

	Hepatitis B
	Neisseria meningitidis

	Varicella zoster virus
	Streptococcus pneumoniae
	Haemophilus influenzae type b

Question 102 of 110

□ □

A 54-year-old alcoholic man with chronic hepatitis C is taken to the emergency department by the police. There it was noted that the man had blisters and crusted lesions on his face and lower arms.

Laboratory tests showed elevated plasma porphyrins and elevated uroporphyrin I in the urine, and isocoproporphyrin in the faeces. Biopsy of the skin lesion showed subepidermal blisters with minimal inflammation, marked solar elastosis, thickening of the vessel wall in the papillary dermis and 'caterpillar bodies' in the roof of the blister.

Which of the following is the most likely diagnosis?

	Acute intermittent porphyria
	Delta-aminolevulinic acid dehydrase deficiency
	Erythropoietic protoporphyria
	Hereditary coproporphyria
	Porphyria cutanea tarda

Question 103 of 110

□ □

A 62-year-old gentleman with a background of Rheumatoid Arthritis, on maintenance sulfasalazine, is referred to the medical take from his GP with severe unremitting flu-like symptoms and deranged blood tests.

On examination, his temperature is 38.3 degrees celsius, heart rate 104bpm, respiratory rate 31/min and oxygen saturations 92% on room air.

His blood test reveals the following:

Hb	82 g/l
Platelets	$52 \times 10^9/l$
WBC	$18 \times 10^9/l$
Ferritin	50,000ng/ml
EBV Monospot test +ve	

He is initially treated as neutropaenic sepsis, with broad spectrum antimicrobials, and transferred to the intensive care unit for organ support. Unfortunately, he does not make any improvement. He is then seen by haematology who organise a bone marrow aspirate, revealing haemophagocytosis. What is the most likely underlying diagnosis?

	Macrophage activation syndrome
	Drug-induced pancytopenia
	Atypical infection
	Parvovirus infection
	Felty syndrome

□ Question 104 of 110

□ □

A 36-year-old female was referred to the outpatient haematology clinic having been referred by her GP with a falling white cell count. Eight weeks ago she saw her own GP complaining of feeling continuously tired after a viral upper respiratory illness two weeks prior to the onset of her symptoms. She also complained of feeling generally unwell and of having intermittent pains in all her joints and muscles without swelling or stiffness. Her respiratory symptoms had fully resolved and she denied any night sweats or weight loss. Her GP organised a set of screening blood investigations which revealed a white cell count of 2.6×10^9 g/dl (neutrophil count 2.0×10^9 g/dl). This was repeated on two further occasions over the next four weeks revealing results of 2.2 and 1.9 respectively (neutrophil counts of 1.5×10^9 g/dl and 1.2×10^9 g/dl respectively). Her past medical history included hypothyroidism for which she was treated with levothyroxine 150mcg OD.

Examination at the clinic revealed the presence of a systemically well female. Her blood pressure was 118/74 mmHg, heart rate 82 bpm, respiratory rate 16/min and temperature 36.6°C . Examination of her cardiovascular system was unremarkable. Similarly, examination of her gastrointestinal system was unremarkable, with no organomegaly identified. No cervical, axillary or inguinal lymph nodes were palpable. Examination of her ENT system was unremarkable.

Initial investigations at the clinic revealed the following results:

Hb	122 g/l
WCC	$2.0 \times 10^9/\text{l}$
Neutrophils	$1.3 \times 10^9/\text{l}$
Lymphocytes	$0.6 \times 10^9/\text{l}$
Monocytes	$0.1 \times 10^9/\text{l}$
Platelets	$224 \times 10^9/\text{l}$
Blood film	neutropaenia
B12	224 (NR 160-900 ng/l)
ESR	15 mm/hr
CRP	9 mg/l

TSH	0.35 (NR 0.4-3.6mu/ml)
FT4	11.6 (NR 4.5-13.6 mcg/dl)
Monospot test	negative
CMV serology	negative

What is the single most appropriate management option?

	Organise bone marrow aspirate and biopsy
	Organise peripheral blood flow cytometry analysis
	Repeat full blood count in four weeks
	Organise CT neck, thorax, abdomen and pelvis
	Organise blood cytogenetic analysis

□ Question 104 of 110

A 36-year-old female was referred to the outpatient haematology clinic having been referred by her GP with a falling white cell count. Eight weeks ago she saw her own GP complaining of feeling continuously tired after a viral upper respiratory illness two weeks prior to the onset of her symptoms. She also complained of feeling generally unwell and of having intermittent pains in all her joints and muscles without swelling or stiffness. Her respiratory symptoms had fully resolved and she denied any night sweats or weight loss. Her GP organised a set of screening blood investigations which revealed a white cell count of 2.6×10^9 g/dl (neutrophil count 2.0×10^9 g/dl). This was repeated on two further occasions over the next four weeks revealing results of 2.2 and 1.9 respectively (neutrophil counts of 1.5×10^9 g/dl and 1.2×10^9 g/dl respectively). Her past medical history included hypothyroidism for which she was treated with levothyroxine 150mcg OD.

Examination at the clinic revealed the presence of a systemically well female. Her blood pressure was 118/74 mmHg, heart rate 82 bpm, respiratory rate 16/min and temperature 36.6°C . Examination of her cardiovascular system was unremarkable. Similarly, examination of her gastrointestinal system was unremarkable, with no organomegaly identified. Question 105 of 110

□ □

A 23-year-old gentleman reviewed by the on-call medical team after having become unwell in the radiology department. He was undergoing a contrast-enhanced MRI of the small bowel to investigate ongoing diarrhoea. He has no other past medical history and takes no regular medications. He is not known to have any allergies.

Ten minutes ago he started feeling his throat closing up and became very anxious. This was shortly after having been given a contrast agent by IV injection. The medical emergency team arrives quickly and note him to be tachycardia at 132/min and hypotensive with a blood pressure of 82/35mmHg. He also has a widespread erythematous rash over his body and feels itchy. He is treated for anaphylactic shock.

Which blood tests could confirm anaphylaxis?

<input type="checkbox"/>	Histamine levels
<input type="checkbox"/>	Mast cell tryptase immediately and repeat within four hour
<input type="checkbox"/>	Mast cell tryptase immediately and repeat within 12 hours
<input type="checkbox"/>	Mast cell tryptase immediately and repeat within 24 hours
<input type="checkbox"/>	Serum immunoglobulins

□ Question 106 of 110

A 75-year-old female is admitted to hospital with community-acquired pneumonia. She is currently being treated with intravenous benzylpenicillin and oral clarithromycin. On the third day of admission, she complains of a sensation of fullness on the lateral aspect of her right leg.

Her past medical history includes osteoarthritis, temporal arteritis (now off steroids) and a uterine prolapse.

Bloods performed the day before show:

Hb	131 g/l
Platelets	$520 \times 10^9/l$
WBC	$14.2 \times 10^9/l$

Na ⁺	141 mmol/l
K ⁺	4.1 mmol/l
Urea	6.2 mmol/l
Creatinine	86 μ mol/l
CRP	78 mg/L

A doppler ultrasound scan is performed that shows a superficial vein thrombosis in the right leg. What is the most appropriate management?

	Treatment dose low molecular weight heparin (LMWH) and warfarin until warfarin therapeutic then anticoagulate for three months
	Prophylactic dose low molecular weight heparin (LMWH) for 30 days.
	Treatment dose low molecular weight heparin (LMWH) for 30 days.

	Non-steroidal anti-inflammatory drugs for 8-12 days.
	Low molecular weight heparin (LMWH) and warfarin until warfarin therapeutic then anticoagulate for six months.

□ Question 107 of 110

□ □

A 77 year old female is referred to the hospitals ambulatory care clinic by her GP after 2 months of increasing generalised malaise and 'lack of energy' over the past two months. She lives with her husband and until 9 weeks ago, continued to drive and go for walks in the countryside with no limitations to her exercise tolerance. Now, she feels 'tired all the time' but denies any problems with her mood. She has no history of psychiatric disorders. Her past medical history includes hypertension (well controlled on ramipril alone), hypercholesterolaemia (well controlled on simvastatin) and chronic lymphocytic leukemia, diagnosed 3 years ago and not requiring treatment.

On examination, she has warm peripheries with bilateral conjunctival pallor. She is alert and comfortable at rest. Non-tender lymphadenopathy in bilateral cervical chains. Her cardiovascular, respiratory, abdominal and neurological examinations are otherwise unremarkable. Her blood results are as follows:

Hb	7.2 g/dl
MCV	101 fl
Platelets	$70 \times 10^9/l$
WBC	$67.0 \times 10^9/l$
Neut	$4.0 \times 10^9/l$
WBC	$62.0 \times 10^9/l$
Reticulocytes	14%
Blood film and direct agglutination test	lymphocytosis, smudge cells, reticulocytes, red cell agglutination at physiological temperature

What is the cause of this patients anaemia?

	Cold autoimmune haemolytic anaemia
	Warm autoimmune haemolytic anaemia
	B12 deficiency anaemia

	Iron deficiency anaemia
	Microangiopathic haemolytic anaemia

□ Question 108 of 110

A 23-year-old man presents to the emergency department acutely unwell for the last 72 hours. He has been fatigued for the last month and has been having night sweats and has had several colds. Over the last 3 days, he has become more unwell, shivery and vomiting. He has noticed bruising on forearms and thighs. On examination, he is drowsy and has a temperature of 38.5°C. His blood pressure is 90/50 mmHg, heart rate 120/min. He is peripherally shut down with a cap refill time of 5 seconds. He has conjunctival pallor. He is given IV fluids and antibiotics by the emergency department. His blood results show:

Hb	89 g/l
Platelets	$43 \times 10^9/l$
WBC	$13.0 \times 10^9/l$
Neutrophils	$9.0 \times 10^9/l$
D-Dimer	5.8mg/L (<0.5)
INR	8.5
PT	89 seconds (9-12)
APTT ratio	1.7 (0.8-1.2)
Fibrinogen	0.1g/L (1.5 - 4.5)
Blood film	Faggot cells seen

Na ⁺	138 mmol/l
K ⁺	5.8 mmol/l
Urea	18 mmol/l
Creatinine	195 µmol/l
CRP	170 mg/l

--	--

Bilirubin	8 µmol/l
ALP	102 u/l
ALT	300 u/l
Albumin	38 g/l

He is transferred to ITU for ionotropic support. He is treated with fresh frozen plasma which corrects his coagulopathy. Haematology is involved and he has a bone marrow analysis performed. Cytogenetics shows a translocation of chromosomes 15 and 17. What is the appropriate treatment to give?

	All-trans retinoic acid
	R-CHOP
	Chlorambucil
	High dose prednisolone
	Ribavirin

A 28-year-old Afro-Caribbean male presents with a two-hour history of sudden onset left sided weakness. He denies any sensory involvement, dysarthria or dysphasia. He has a known history of sickle cell disease, with two previous episodes of transient ischaemic attacks and an episode of acute chest syndrome attack 10 days ago. On examination, he displays power of 1/5 in his left arm, 2/5 in his left leg, 5/5 in his right side. He reports no sensory disturbances, plantar responses are downgoing bilaterally, he is unable to perform finger-nose testing. He denies any illicit drug use, is a non-smoker and does not drink alcohol. He has no other past medical history. A hyperacute CT head demonstrates an area of acute ischaemia in the right internal capsule region. What is the most appropriate immediate treatment?

	Intravenous thrombolysis
	Aspirin 300mg
	Intravenous thrombolysis and mechanical thrombectomy
	Exchange transfusion
	Clopidogrel 300mg

□ Question 110 of 110

□ □

A 66-year-old gentleman was admitted for an elective aortic valve replacement. His past medical history included a non-ST elevation myocardial infarction three years prior, as well as hypertension and hypercholesterolaemia. He also suffered a deep vein thrombosis 16 years ago after open reduction and internal fixation of a tibial fracture requiring treatment with warfarin postoperatively. There was no family history of note. He was currently taking aspirin 75mg OD, clopidogrel 75mg OD, ramipril 5mg OD, bisoprolol 2.5mg OD, atorvastatin 20mg ON and lansoprazole 15mg OD.

Two days prior to the operation the patient was commenced on an intravenous heparin infusion which was continued perioperatively. The operation was deemed successful and the infusion was discontinued. He was commenced on enoxaparin 40mg OD sc as prophylaxis for venous thromboembolism postoperatively. He was otherwise making a good post operative recovery and was already mobilising readily. He complained of no chest pain or shortness of breath with no syncopal episodes. He resumed a full and normal diet and his bowel habits were normal. There was no evidence of bleed or any other adverse symptoms.

Routine post operative bloods at day 5 were as follows:

Hb	110 g/l
MCV	81 fl
Haematocrit	0.36
Platelets	28* 10 ⁹ /l
WBC	9.0 * 10 ⁹ /l
PT	36 seconds
APTT	86 seconds
D-dimer	136 ng/mL
Fibrinogen	236 g/L

Na ⁺	142 mmol/l
K ⁺	4.5 mmol/l

Urea	6.3mmol/l
Creatinine	77 µmol/l
Bilirubin	17 µmol/l
ALP	101 u/l
ALT	16 u/l
Albumin	39 g/l

Blood tests at day 2 were as follows:

Hb	116 g/l
Platelets	161 * 10 ⁹ /l
WBC	10.0 * 10 ⁹ /l

What is the single most appropriate management step?

<input type="radio"/>	Stop heparin and commence treatment with vitamin K
<input type="radio"/>	Continue with enoxaparin
<input type="radio"/>	Stop all anticoagulation until platelet count is >100 x 10 ⁹ /l
<input type="radio"/>	Stop enoxaparin and commence danaparoid
<input type="radio"/>	Stop enoxaparin and commence warfarin

□ Question 1 of 155

A 49-year-old man attends the emergency department after becoming unwell with symptoms of progressive shortness of breath. The man is a Saudi Arabian national, who arrived in the UK 3 days previously on a business trip. The patient reported his shortness of breath had gradually worsened over the previous 2 days to the point whereby even minor physical activity had become challenging. In addition, the patient had noticed a dry cough, runny nose, myalgia and fever over a similar period. The patient denied any history of a productive cough, haemoptysis or gastrointestinal symptoms.

The patient reported being in generally good health aside from the type 2 diabetes mellitus and hypertension. To control these conditions, the patient took regular metformin and captopril. The patient had no known allergies to medications. The patient worked as an international businessman and normally resided in Riyadh with his family. He denied any contact with domestic animals in recent months and had not knowingly spent time with any unwell contacts.

General examination of the patient revealed a slightly overweight middle aged man who appeared unwell and diaphoretic. Basic physical observations are recorded in the below table. Examination of the respiratory system revealed mild tachypnoea at rest but with unremarkable percussion and auscultation of both lung fields. Examinations of the cardiovascular and abdominal systems were unremarkable. No clinical evidence of deep vein thrombosis was identified. Please see below for results of initial investigations requested following assessment by the respiratory medicine team.

Heart rate	95 beats / minute
Respiratory rate	23 respirations / minute
Blood pressure	128 / 85 mmHg
Oxygen saturations (room air)	89 %
Oxygen saturations (O ₂ 3 L / minute via nasal cannulae)	95 %
Glasgow coma scale score	15

Haemoglobin	145 g / dL
Mean cell volume	80.2 fl
White cell count	3.1 x 10 ⁹ / microlitre

Lymphocytes	1.0 x 10 ³ / microlitre (reference 1.5-4.0)
Platelets	115 x 10 ³ / microlitre
Urea	6.4 mmol / L
Creatinine	85 micromol / L
eGFR	85 ml / min / 1.73 m ²
Sodium	139 mmol / L
Potassium	4.0 mmol / L
C-reactive protein	74 mg / L (reference < 7)
Urinalysis	no abnormality detected
Chest x-ray	no pneumothorax; lung fields generally clear with no focal consolidation; no mass lesions
Electrocardiogram	normal sinus rhythm
Nasopharyngeal swab RT-PCR	MERS-CoV RNA detected

What is appropriate medical management for the patient's condition?

	Treatment in the community with anti-pyretic
	Intravenous ganciclovir (5 mg / kg twice daily for 14 days)
	In-patient supportive treatment to relieve symptoms and prevent or treat complications
	Oral oseltamivir (75 mg twice daily for 5 days)
	Inhaled zanamivir (10 mg twice daily for 5 days)

Question 2 of 155

A 72-year-old lady was admitted with a cough productive of green phlegm, shortness of breath and a low-grade fever. Past medical history included Parkinson's disease for which she was on co-careldopa and hypertension. Chest x-ray showed a right basal consolidation and she was treated for pneumonia with oral antibiotics. As a result of the pneumonia she had a poor appetite and the patient had been refusing to take her medication.

She was given intravenous fluids and encouraged to take her oral antibiotics. Over the next 1-2 days, the nurses noted that she had started to have fever spikes of greater than 38°C, had developed a tremor and was becoming increasingly rigid, agitated and confused. Her blood pressure had also been extremely variable.

What test would help you confirm the diagnosis?

	Repeat chest x-ray
	Creatine kinase
	Blood cultures
	CT head
	Urine sample

Dashboard

Overall score: 0%

A 72-year-old lady was admitted with a cough productive of green phlegm, shortness of breath and a low-grade fever. Past medical history included Parkinson's disease for which she was on co-careldopa and hypertension. Chest x-ray showed a right basal consolidation and she was treated for pneumonia with oral antibiotics. As a result of the pneumonia she had a poor appetite and the patient had been refusing to take her medication.

She was given intravenous fluids and encouraged to take her oral antibiotics. Over the next 1-2 days, the nurses noted that she had started to have fever spikes of greater than 38°C, had developed a tremor and was becoming increasingly rigid, agitated and confused. Her blood pressure had also been extremely variable.

What test would help you confirm the diagnosis?

	Repeat chest x-ray
	Creatine kinase
	Blood cultures
	CT head
	Urine sample

□ Question 3 of 155

A 31-year-old gentleman presents with fever, headache, abdominal pain and a rash on the chest 3 weeks after visiting South America.

On examination the temperature is 38.2°C. There is a rash on the chest consisting of rose-coloured blanching papules. The respiratory rate is 20 breaths/min and the heart rate is 58 beats per minute. The chest is clear to auscultation. The abdomen is diffusely tender and there is mild splenomegaly.

Initial blood results are as follows:

Hb	128 g/l
Platelets	184 * 10 ⁹ /l
WBC	3.9 * 10 ⁹ /l
Na ⁺	131 mmol/l
K ⁺	3.3 mmol/l
Urea	7.2 mmol/l
Creatinine	141 µmol/l
Bilirubin	46 µmol/l
ALP	147 u/l
ALT	96 u/l
Albumin	38 g/l
CRP	52 mg/l

What is the most appropriate initial antimicrobial therapy?

	Ampicillin

	Chloramphenicol
	Trimethoprim-sulfamethoxazole
	Cefotaxime
	Streptomycin

Question 5 of 155

□ □

A 27 year old Caucasian man has just returned from a 12 week trip to Ivory Coast where he was working as a missionary. He had not consulted a travel clinic for immunisations and had taken no malaria prophylaxis. During his trip he slept in a hammock outside and he took a daily wash in the river near the church where he was working. For the last few days of his trip he felt very unwell. He developed fevers, muscle aches and a headache, however this was improving and he had been feeling much better when he arrived home in the UK.

He has been home for 24 hours. Today he felt very much worse and presented to A and E.

On admission:

- Temperature: 39.1C
- Blood pressure: 89/61mmHg
- Pulse: 68 / min
- Respiratory rate: 26 / min
- Oxygen saturations: 97% on room air.

His initial investigations show:

Hb	11.1 g/dl
Platelets	61 * 10 ⁹ /l
WBC	3.3 * 10 ⁹ /l
Neutrophils	2.6 * 10 ⁹ /l
Lymphocytes	0.6 * 10 ⁹ /l

Na ⁺	146 mmol/l
K ⁺	4.1 mmol/l
Bicarbonate	16 mmol/l
Urea	17.4 mmol/l

Creatinine	321 mol/l
------------	-----------

Bilirubin	88 mol/l
ALP	322 u/l
ALT	821 u/l
γGT	421 u/l
Albumin	29 g/l

Following discussion with the ID consultant on call, he is isolated while a blood sample is sent to Public Health England's imported fever service. He received empirical therapy for Malaria with Artesunate and for sepsis with Piperacillin/Tazobactam and Gentamicin, however he rapidly deteriorated and died within 24 hours of admission. Following discussion with Public Health England, who confirm that there was no evidence of a nosocomially transmitted Viral Haemorrhagic Fever, he has a post mortem examination which reveals Councilman bodies in his liver.

What would likely have prevented his death?

	Sleeping under an insecticide treated bed net
	Avoiding bathing in the river
	Live attenuated Yellow Fever vaccine
	Prophylaxis with doxycycline
	Avoiding unprotected sex

□ Question 7 of 155

□ □

A 19-year-old from Cameroon has moved to the UK to study nursing. She arrived three months ago. She has been having diarrhoea for a month and noticed a fleeting erythematous rash on her torso. Her GP orders a set of bloods, which reveal a dramatic eosinophilia. She has not lost weight and, if anything, seems concerned that she is becoming overweight since moving to the UK. She has been well previously with no allergies or medication. There is no significant family history but she tells you that her brother had an 'eye worm' last year.

A stool is sent for ova cysts and parasites and microscopy and culture. Multiple *Strongyloides stercoralis* larvae can be seen on charcoal culture. She is commenced on a seven-day course of Ivermectin.

Four days later she is brought into the Emergency Department, with a GCS of 6.

What is the diagnosis?

	Disseminated <i>Strongyloides</i> infection
	Co-infection with Onchocerciasis
	Co-infection with Loa
	Ivermectin related hypoglycaemia
	Insulin abuse

□ Question 8 of 155

□ □

A 37-year-old gentleman presents to the Emergency Department with acute onset shortness of breath and right sided pleuritic chest pain. He is known to be HIV positive and his latest CD4 count is 190/mm³. The last clinic letter suggests he may be non-compliant with his anti-retroviral medication due to persistent diarrhoea. On examination, he has decreased breath sounds on the right with fine scattered crepitations in both lung fields. Oxygen saturations are 93% on breathing air. A chest x-Ray reveals a right sided pneumothorax measuring 1 cm at the hilum.

What pulmonary infection would you suspect?

	<i>Mycobacterium tuberculosis</i>
	<i>Pneumocystis jirovecii</i>
	<i>Aspergillus fumigatus</i>
	<i>Histoplasma capsulatum</i>
	<i>Haemophilus influenzae</i>

□ Question 9 of 155

A 32-year-old lady presented after returning from Nigeria 3 weeks ago to her GP complaining of feeling feverish and pain in her joints making walking difficult. She denied any rash, or headaches however she has been very drowsy and lethargic in the past week. She spent a week in Nigeria and visited her relatives both in urban and rural areas. She has been taking her malaria prophylaxis tablets. She denies being sexually active for the past year. Her GP sent off three malaria screens which were negative.

Two months later she represents to the emergency department following a seizure and is found to be confused and disorientated. She is irritable, and you notice her hand is trembling. Her sister says she has lost her appetite and weight and has been behaving strangely in the past month. She spends most of her time in bed during the day complaining of a headache and has become withdrawn. On examination, there is hypertonia in her limbs, with hyperreflexia, but the rest of examination is difficult as she is uncooperative.

Investigations:

Na ⁺	140mmol/l
K ⁺	4.3 mmol/l
Urea	5.3 mmol/l
Creatinine	85 µmol/l
Serum bilirubin	15 µmol/l
Serum alkaline phosphatase	85 IU/l
Serum aspartate aminotransferase	19 IU/l
Serum Albumin	25 g/l
C Reactive protein (CRP)	25 mg/l
Erythrocyte Sedimentation Rate (ESR)	75 mm/hr
Haemoglobin	96 g/l
White cell count	10.2 x 10 ⁹ /L
Neutrophils	8.9 x 10 ⁹ /L

Eosinophilia	0.1 x10 ⁹ /L
Lymphocytes	1.8 x 10 ⁹ /L
Platelets	140 x 10 ⁹ /L
INR	1.0

What is the likely causative organism?

	<i>Plasmodium vivax</i>
	<i>Borrelia burgdorferi</i>
	<i>Trypanosoma gambiense</i>
	<i>Trypanosoma rhodesiense</i>
	<i>Trypanosoma cruzi</i>

Question 10 of 155

□ □

A 32-year-old South African man presents to the rheumatology clinic for review. He was diagnosed with ankylosing spondylitis 5 years ago and subsequently failed on a course of NSAIDs and an extended course of glucocorticoids. He was therefore started on Etanercept 1 year ago and had reported a significant reduction in his symptoms.

Today he reports an increase in lethargy over the last 2 months. This has been associated with a degree of breathlessness, a dry cough and weight loss that he is unable to quantify.

When you come to examine him you notice a tender swelling over the sternum. The patient admits to falling off his bike recently and jarring the handle bars into his chest. Further examination reveals a soft, cool, fluctuant swelling over the mid sternum. There is a small break in the skin with surrounding erythema. Respiratory examination reveals a reduced expansion with some upper zone crackles.

What is the likely diagnosis?

	Pathological fracture secondary to glucocorticoid use
	Localised cellulitis
	Tuberculosis
	Restrictive lung disease secondary to costovertebral involvement of ankylosing spondylitis
	Upper lobe pulmonary fibrosis

Dashboard

□ Question 11 of 155

A 65-year-old man is undergoing treatment in the intensive care unit. He had presented 8 days previously after suffering a seizure at home. He had been unable to give a coherent history at the time of presentation but his family had reported he had been unwell for about two weeks. Initial symptoms included a fever, myalgia, anorexia and an intense itching of his left arm. Subsequently, the patient had developed progressive confusion and agitation and was incoherent by the time of presentation to hospital. The patient was a long-term resident of the UK, but had made a trip back to his native India around 6 months previously. During that trip, his wife recalled the patient being bitten by a dog in his family village, although the wound had been minor and healed without incident after basic first aid. Medical history was otherwise fairly unremarkable, including hypertension, tablet-controlled type 2 diabetes and gout.

At presentation, the patient had been noted to be highly agitated and disorientated. Hypersalivation was noted and patient had been refusing to eat or drink. Examination had been limited by the patient's agitation but no overt focal neurological symptoms were noted in the cranial nerve or peripheral nervous examination. After the patient had been sedated, it was noted that striking a large muscle group with a tendon hammer led to few seconds of mounding of the muscle.

CSF protein	457 g / dL
CSF Microscopy	NAD
CSF rabies virus neutralising antibodies	Not detected
Serum rabies virus neutralising antibodies	Detected

At the present time, the patient is receiving end-of-life care. He is sedated and appears comfortable secondary to midazolam delivered by a syringe driver. His family wish to be present at his bedside.

What is the appropriate personal protection for healthcare workers and family members to use while in contact with the patient?

	High isolation
	Standard precautions
	Respiratory isolation

	Reverse isolation
	Biocontainment precautions

Dashboard

Overall score: **0%**

□ Question 12 of 155

A 38-year-old male presented to the Emergency Department complaining of feeling unwell. He complained of a headache that had been present for the last two days which he described a continuous ache worse in the morning, as well as a sore throat. He later developed diarrhoea, opening his bowels three times per day passing watery loose stool. Since then he has deteriorated, complaining of nausea and vomiting on the day of admission. He also noted a new rash on his chest which developed over the last few hours and complained of pains in his muscles. He had returned two weeks ago from a six-month backpacking expedition around Africa and Far East Asia; he was prescribed doxycycline as antimalarial prophylaxis but had discontinued them two weeks into his trip after suffering from severe sunburns. He had not taken recommended vaccinations prior to his trip as he was engaged with work commitments. His past medical history comprised of asthma and depression for which he was prescribed sertraline 100mg OD and Clenil modulite 2 puffs BD.

Examination revealed the presence of an unwell gentleman. His temperature was 40.1°C, heart rate 122 bpm, respiratory rate 22/min, oxygen saturations 95% on air and he had a blood pressure of 94/68 mmHg. He had a plethoric facial appearance, and multiple petechiae were noted on his chest and face. Examination of his cardiovascular system revealed the presence of normal heart sounds with a JVP of 2cm and a bounding radial pulse and vasodilated peripheries. Examination of his respiratory system revealed tachypnoea but with vesicular breath sounds. Examination of the gastrointestinal and neurological systems was unremarkable, with no neck stiffness, negative Kernig's and Brudzinski's signs. His GCS was 15. Multiple insect bites were noted on his legs and arms.

He was promptly transferred to the resuscitation area where two large bore cannulae were inserted and aggressive intravenous fluid resuscitation was commenced. A urinary catheter was inserted. The doctor inserting the cannulae noted that the sites of venepuncture continued to ooze despite the application of continual mechanical pressure.

Initial investigations revealed the following results:

Hb	102 g/l
Platelets	$8 \times 10^9/l$
WBC	$3.2 \times 10^9/l$
Neutrophils	$2.2 \times 10^9/l$
Lymphocytes	$0.8 \times 10^9/l$

Monocytes	0.1 * 10 ⁹ /l
Eosinophils	0.1 * 10 ⁹ /l
ESR	48 mm/hr

PTT	17 (NR 12-14s)
APTT	53 (NR 30-46s)
Fibrinogen	0.6 (NR 2-4g/l)
D-Dimer	428 (NR <230ng/ml)

Na ⁺	130 mmol/l
K ⁺	6.2 mmol/l
Urea	18.1 mmol/l
Creatinine	262 µmol/l
CRP	96 mg/l

Bilirubin	28 µmol/l

□ Question 12 of 155

A 38-year-old male presented to the Emergency Department complaining of feeling unwell. He complained of a headache that had been present for the last two days which he described a continuous ache worse in the morning, as well as a sore throat. He later developed diarrhoea, opening his bowels three times per day passing watery loose stool. Since then he has deteriorated, complaining of nausea and vomiting on the day of admission. He also noted a new rash on his chest which developed over the last few hours and complained of pains in his muscles. He had returned two weeks ago from a six-month backpacking expedition around Africa and Far East Asia; he was prescribed doxycycline as antimalarial prophylaxis but had discontinued them two weeks into his trip after suffering from severe sunburns. He had not taken recommended vaccinations prior to his trip as he was engaged with work commitments. His past medical history comprised of asthma and depression for which he was prescribed sertraline 100mg OD and Clenil modulite 2 puffs BD.

Examination revealed the presence of an unwell gentleman. His temperature was 40.1°C, heart rate 122 bpm, respiratory rate 22/min, oxygen saturations 95% on air and he had a blood pressure of 94/68 mmHg. He had a plethoric facial appearance, and multiple petechiae were noted on his chest and face. Examination of his cardiovascular system revealed the presence of normal heart sounds with a JVP of 2cm and a bounding radial pulse and vasodilated peripheries. Examination of his respiratory system revealed tachypnoea but with vesicular breath sounds. Examination of the gastrointestinal and neurological systems was unremarkable, with no neck stiffness, negative Kernig's and Brudzinski's signs. His GCS was 15. Multiple insect bites were noted on his legs and arms.

He was promptly transferred to the resuscitation area where two large bore cannulae were inserted and aggressive intravenous fluid resuscitation was commenced. A urinary catheter was inserted. The doctor inserting the cannulae noted that the sites of venepuncture continued to ooze despite the application of continual mechanical pressure.

Initial investigations revealed the following results:

Hb	102 g/l
Platelets	$8 \times 10^9/l$
WBC	$3.2 \times 10^9/l$
Neutrophils	$2.2 \times 10^9/l$
Lymphocytes	$0.8 \times 10^9/l$

Monocytes	0.1 * 10 ⁹ /l
Eosinophils	0.1 * 10 ⁹ /l
ESR	48 mm/hr

PTT	17 (NR 12-14s)
APTT	53 (NR 30-46s)
Fibrinogen	0.6 (NR 2-4g/l)
D-Dimer	428 (NR <230ng/ml)

Na ⁺	130 mmol/l
K ⁺	6.2 mmol/l
Urea	18.1 mmol/l
Creatinine	262 µmol/l
CRP	96 mg/l

Bilirubin	28 µmol/l
ALP	162 u/l
ALT	122 u/l
Total protein	52 g/l
Albumin	22 g/l

□ Question 13 of 155

A 40-year-old man attends the emergency department with a 3-day history of worsening respiratory symptoms. The patient reported that his initial symptoms had included a runny nose, sore throat and myalgia. Subsequently, he developed a persistent dry cough and had experienced mild shortness of breath on exertion, for example after climbing a flight of stairs. The patient had not measured his temperature at home but recalled that, at times, he had felt extremely hot and sweaty. The patient denied any other symptoms, including a cough productive of sputum or blood, abdominal symptoms or chest pain.

The patient reported having just returned from a 2 week holiday in Egypt. The majority of the patient's trip had been based in large towns and cities; however, the patient had also participated in a 4-day 'camel trek' through the desert. On direct questioning, the patient reported having drunk camel milk offered to him by his guides, which he did not think had been pasteurised or otherwise processed prior to consumption. The patient had not knowingly spent time around any unwell individuals and had not sought medical advice while overseas. Prior to this holiday, the patient had not travelled outside of the UK for several years.

The patient was in generally good health, with no active chronic medical problems. The patient's only previous attendance at the emergency department was 5 years previously when he had treated for a broken ankle sustained when playing football. The patient took no regular medications and had no known allergies to medications. The patient did not regularly consume alcohol or recreational drugs but did smoke 5-10 cigarettes per day.

General examination of the patient showed a middle-aged man who appeared flushed in the face and unwell. Examination of the respiratory system demonstrated normal air entry and resonance to both lung fields, with no significant added sounds on auscultation. With the patient at rest, there were no signs of respiratory distress. Examination of the cardiovascular and abdominal systems demonstrated no significant abnormality. There was no notable rashes and no signs of peripheral deep vein thrombosis.

Heart rate	92 beats / minute
Respiratory rate	18 respirations / minute
Blood pressure	125 / 76 mmHg
Oxygen saturations	95 %
Glasgow coma scale score	15
	o

Temperature	38.2 C
-------------	--------

Haemoglobin	135 g / dL
White cell count	3.7 x 10 ³ / microlitre
Neutrophils	2.5 x 10 ³ / microlitre (reference 1.8-7.8)
Lymphocytes	1.0 x 10 ³ / microlitre (reference 1.5-4.0)
Platelets	123 x 10 ³ / microlitre
Urea	6.1 mmol / L
Creatinine	82 micromol / L
Alkaline phosphatase	154 U / L (reference 35-100)
ALT	72 U / L (reference 3-36)
Bilirubin	23 micromol / L (reference < 26)
Chest x-ray	clear lung fields, no pneumothorax

What is the likely pathogen responsible for the patient's illness?

	MERS coronavirus
	Dengue virus
	West Nile virus
	Junin virus
	Ebola virus

Dashboard

Overall score: **0%**

□ Question 14 of 155

□ □

A 21-year-old male presents on the medical take with fever, rigors and a headache which started yesterday. He returned from a 2 week trip travelling across south east Asia 5 days ago. His last destination was Bangkok and prior to this he had been in the mostly rain forested area of northern Thailand. His symptoms started around 5 days after arriving in Thailand.

He did not take malaria prophylaxis during the trip but had received all the recommend vaccinations. He travelled with his long-term girlfriend and he reports always using condoms during intercourse.

On examination he has a fever of 38.9°C, a pulse of 92 beats per minute, blood pressure of 115/80 mmHg, oxygen saturations of 99% on air. There is an area of confluent blanching erythema over the precordium and fundoscopy was poorly tolerated due to pain.

What is the most likely diagnosis?

	Dengue fever
	HIV seroconversion
	Malaria
	Typhoid
	Infectious mononucleosis

Dashboard

Overall score: **0%**

□ Question 19 of 155

You are called to the Emergency Department to review a 60-year-old Indian female who returned from a six month trip to the north east of India five days ago. She presented with a three week history of a productive cough, producing large quantities of brown sputum. She has also been experiencing fevers daily and complains of being extremely sweaty over night. On further questioning there is no history of weight loss or TB contacts. The patient reports that as she has felt relatively well with these symptoms she had not presented earlier. It was, in fact a concerned relative who thought the patient had coughed up blood who had brought her in to hospital today.

Examination reveals a comfortable patient with evidence of a right lower zone pneumonia. The is confirmed on chest radiograph. You send a number of investigations including sputum for routine culture and acid fast bacilli. The results of which are shown below:

Hb	120 g/l	Na ⁺	139 mmol/l
Platelets	350 * 10 ⁹ /l	K ⁺	3.9 mmol/l
WBC	13.0 * 10 ⁹ /l	Urea	8.0 mmol/l
Neuts	8.0 * 10 ⁹ /l	Creatinine	110 µmol/l
Lymphs	1.5 * 10 ⁹ /l	CRP	35 mg/l
Eosin	1.8 * 10 ⁹ /l		
Sputum MC&S	Negative		
Sputum TB PCR	Negative		

What is the most appropriate treatment for this patient?

	Rifater and ethambutol
	Amoxicillin
	Praziquantel

	Augmentin and clarithromycin
	Fluconazole

Dashboard

Overall score: **0%**

A 57-year-old man who just returned from a cruise to the Bahamas comes to the emergency department with fever, non-productive cough and shortness of breath for the past 2 days. He has also had a headache, abdominal pain and diarrhoea since yesterday. The patient has a history of type 2 diabetes mellitus, and a smoking history of 20 pack-years. He does not use alcohol or illicit drugs. His temperature is 39.2°C, blood pressure is 110/65 mmHg, pulse is 80/min and respirations are 18/min. Pulse oximetry shows 97% on room air.

Lung examination demonstrates crackles bilaterally. The abdomen is soft and non-tender. The patient seems confused at times during the examination. His serum glucose is normal; serum sodium is 128 mmol/l. Chest x-ray demonstrates bilateral interstitial infiltrates. He is admitted to the ward.

Which of the following antibiotics should be given to this patient?

	Co-amoxiclav
	Ceftriaxone
	Clindamycin
	Levofloxacin
	Vancomycin

Question 22 of 155

A 57-year-old man who just had a productive cough and shortness of breath since yesterday. He has no fever, no diarrhoea since yesterday. He does not use alcohol or tobacco. His respiratory rate is 18/min. Pulse is 98/min.

Lung examination demonstrates hyperinflation. At times during the examination, there are bilateral interstitial infiltrates.

Which of the following antibiotics is most appropriate?

<input type="radio"/>	Co-amoxiclav
<input type="radio"/>	Ceftriaxone
<input type="radio"/>	Clindamycin
<input checked="" type="radio"/>	Levofloxacin
<input type="radio"/>	Vancomycin

□ Question 22 of 155

□ □

A 57-year-old man who just returned from a cruise to the Bahamas comes to the emergency department with fever, non-productive cough and shortness of breath for the past 2 days. He has also had a headache, abdominal pain and diarrhoea since yesterday. The patient has a history of type 2 diabetes mellitus, and a smoking history of 20 pack-years. He does not use alcohol or illicit drugs. His temperature is 39.2°C, blood pressure is 110/65 mmHg, pulse is 80/min and respirations are 18/min. Pulse oximetry shows 97% on room air.

Lung examination demonstrates crackles bilaterally. The abdomen is soft and non-tender. The patient seems confused at times during the examination. His serum glucose is normal; serum sodium is 128 mmol/l. Chest x-ray demonstrates bilateral interstitial infiltrates. He is admitted to the ward.

Which of the following antibiotics should be given to this patient?

	Co-amoxiclav
	Ceftriaxone
	Clindamycin
	Levofloxacin
	Vancomycin

Question 23 of 155

□ □

A 98-year-old lady presents with a fever and confusion and on initial review is started on broad spectrum antibiotics. Despite five days of therapy, her temperature is 38.9°C and her clinical condition seems to have deteriorated. She has no relevant past medical history. The diagnosis of urinary tract infection (UTI) is confirmed when urine cultures confirm an extended spectrum B-lactamase (ESBL) producing *Escherichia coli* (E. coli).

Following the failure to respond to the first-line agent, which antibiotic is most likely to be effective?

	Trimethoprim
	Tetracycline
	Amoxicillin
	Cefalexin
	Ertapenem

□ Question 24 of 155

A 36-year-old Sri-Lankan woman presents to the GP with a malar rash. On examination she has a erythematous rash that is warm to touch with some underlying oedema over both cheeks and the bridge of her nose.

She reports feeling low in energy over several months and describes a feeling of numbness in her feet and hands.

Investigations:

haemoglobin	125 g/L (115-165)
white cell count	9.4 × 10 ⁹ /L (4.0-11.0)
platelet count	220 × 10 ⁹ /L (150-400)
erythrocyte sedimentation rate	50 mm/1st h (<30)
serum urea	7.0 mmol/L (2.5-7.0)
serum creatinine	105 mol/L (60-110)
serum alanine aminotransferase	17 U/L (5-35)
serum aspartate aminotransferase	26 U/L (1-31)
serum complement C3	80 mg/dL (65-190)
serum complement C4	45 mg/dL (15-50)
serum C-reactive protein	145 mg/L (<10)
anti-double-stranded DNA antibodies	negative
c-ANCA	negative
p-ANCA	negative
antinuclear antibodies	1:20 (negative at 1:20 dilution)

An outpatient rheumatology appointment is arranged and she is started on a course of steroids in the interim. Her symptoms rapidly improve and the rash almost completely resolves however she is left with persistent numbness that appears to be worsening.

What is the most likely underlying diagnosis?

	Granuloma annulare
	Annular psoriasis
	Systemic lupus erythematosus
	Leprosy
	Cutaneous leishmaniasis

□ Question 25 of 155

A 35 year-old Brazilian accountant presented to the medical outpatient clinic with progressive leg swelling over the last 18 months. His mobility had become increasingly restricted due to both the swelling and shortness of breath on exertion. His father and paternal grandfather had both died from ischaemic heart disease in their 60s. His past medical history was unremarkable. He had smoked 15 cigarettes a day for 15 years and drank 15 units of alcohol per week.

On examination, his temperature was 36.5°C, blood pressure was 95/50 mmHg and heart rate was 75 beats per minute. His JVP was elevated to the angle of the jaw. His chest was clear on auscultation, but a third heart sound and pan-systolic murmur were audible on auscultation of the precordium. Bilateral pitting oedema to mid-thigh level was present.

Investigations:

Haemoglobin	131 g/L (130-180)
White cell count	6.9 x 10 ⁹ /L (4.0-11.0)
Neutrophil count	3.1 x 10 ⁹ /L (2.0-7.5)
Lymphocyte count	1.9 x 10 ⁹ /L (1.3-3.5)
Eosinophil count	1.1 X 10 ⁹ /L (0.1-0.4)
Platelets	260 x 10 ⁹ /L (150-400)

Sodium	132 mmol/L (135-145)
Potassium	3.6 mmol/L (3.5-5.0)
Urea	8.0 mmol/L (2.5-7.5)
Creatinine	101 mol/L (20-90)
Fasting plasma glucose	7.2 mmol/L (3.0-6.0)

Echocardiogram	Moderately impaired left ventricular systolic function Dilated left ventricle with moderate mitral regurgitation
----------------	---

What is the most appropriate treatment for the underlying condition?

	Sulfadiazine and pyrimethamine
	Doxycycline
	Artesunate
	Benznidazole
	Mebendazole

□ Question 27 of 155

A 50-year-old man presents to the Emergency Department after becoming increasingly unwell over the previous two weeks. His initial symptoms were fevers increasing shortness of breath. In the last 24 hours he had experienced several episodes of haemoptysis and bloody diarrhoea precipitating his attendance to hospital.

Past medical history included a diagnosis of systemic lupus erythematosus five years previously. This disease had been poorly controlled in recent months requiring the patient to take prednisolone 40 mg daily and hydroxychloroquine 400 mg daily. The patient was originally from Mali and had emigrated to the UK twenty years previously. He had returned to visit family in Africa earlier in the year and had not taken malaria prophylaxis whilst abroad.

Initial assessment revealed the patient to be very unwell. Respiratory rate was 32 with O₂ saturations of 94 % on high flow oxygen. Blood pressure was 80/50 mmHg with no improvement in hypotension following aggressive fluid resuscitation. The patient was intubated and ventilated and transferred to the Intensive Care Unit for inotropic support.

Results of immediate investigations are listed below.

Chest x-ray: widespread diffuse pulmonary infiltrates; left sided pleural effusion; no free air under the diaphragm

Abdominal x-ray: multiple loops of distended small bowel; no evidence of free air

Hb	11.2 g/dl
Mean cell volume	83 fL
Platelets	$150 \times 10^9/l$
WBC	$18.7 \times 10^9/l$
Neutrophils	$14.8 \times 10^9/l$
Lymphocytes	$2.0 \times 10^9/l$
Monocytes	$1.0 \times 10^9/l$
Eosinophils	$0.9 \times 10^9/l$
Blood film	no abnormality detected
Internationalised normalised ratio	1.2

Na ⁺	124 mmol/l
K ⁺	4.9 mmol/l
Urea	15 mmol/l
Creatinine	190 µmol/l
C-reactive protein	284 mg/dL

Blood cultures: Gram negative cocci (positive after 24 hours)

Pleural fluid microscopy: filariform larvae

What is the most likely underlying diagnosis?

<input type="radio"/>	Caecal carcinoma
<input type="radio"/>	Strongyloides hyperinfection syndrome
<input type="radio"/>	Churg-Strauss vasculitis
<input type="radio"/>	Plasmodium falciparum infection
<input type="radio"/>	Disseminated haematogenous tuberculosis

Question 28 of 155

A 30-year-old male refugee presents with fever, rigours and right flank pain. With the help of a translator you discover he has been unwell for 7 days with these symptoms that are getting progressively worse. He says he is otherwise fit and well and does not take any regular medications. He moved to the UK 2 months ago having lived his entire life in Sudan.

On examination he has a temperature of 38.2 degrees, a heart rate of 98 beats per minute, a blood pressure of 110/70 and a respiratory rate of 20. He is lying calmly in the bed but is tender over the renal angle on the right side.

Investigations:

serum sodium	138 mmol/L (137-144)
serum potassium	5.5 mmol/L (3.5-4.9)
serum creatinine	240 mol/L (60-110)
haemoglobin	98 g/L (130-180)
white cell count	15.4 × 10 ⁹ /L (4.0-11.0)
eosinophil count	0.89 × 10 ⁹ /L (0.04-0.40)
platelet count	378 × 10 ⁹ /L (150-400)
urine microscopy	red cells 2+, white cells 3+, protein 2+
ultrasound scan of abdomen	right sided hydronephrosis and hydroureter, fibrotic and calcified bladder

What is the most likely underlying diagnosis?

	<i>Schistosomiasis japonicum</i>
	Chronic vesico-ureteric reflux and secondary pyelonephritis

	Squamous cell carcinoma of the bladder
	<i>Schistosomiasis haematobium</i>
	<i>Schistosomiasis mansoni</i>

□ Question 31 of 155

A 44 year-old lady presented to the medical outpatient clinic with leg swelling which had progressively increased over the last 2 years. Her past medical history consisted only of a hospital admission for malaria as a child. She had grown up in urban Nigeria and moved to the United Kingdom 6 years ago to work as a teacher, but had been forced to stop working due to mobility problems. She was a non-smoker and did not drink alcohol.

On examination, her temperature was 36.5°C, heart rate 80 beats per minute, blood pressure 133/89 mmHg, respiratory rate 16 breaths per minute and oxygen saturations 98% on room air. Non-pitting leg swelling was apparent bilaterally extending proximally to the hips, with thickening of the overlying skin. Her chest was clear on auscultation and heart sounds were normal. The JVP was not elevated.

Investigations:

Haemoglobin	138 g/L
White cell count	$7.0 \times 10^9/l$
Neutrophil count	$4.8 \times 10^9/l$
Lymphocyte count	$2.0 \times 10^9/l$
Eosinophil count	$0.1 \times 10^9/l$
Platelets	$246 \times 10^9/l$

Sodium	142 mmol/L
Potassium	4.3 mmol/L
Urea	6.0 mmol/L
Creatinine	84 mol/L
Alkaline phosphatase	40 IU/L
Alanine aminotransferase	32 IU/L
Gamma-glutyl transferase	23 IU/L

Bilirubin	16 mol/L
Albumin	41 g/L
Fasting plasma glucose	5.3 mmol/L

What is the most likely causative organism?

	<i>Wuchereria bancrofti</i>
	<i>Brugia malayi</i>
	<i>Brugia timori</i>
	<i>Onchocerca volvulus</i>
	<i>Mansonella streptocerca</i>

□ Question 32 of 155

□ □

A 38-year-old woman presents to her HIV clinic for her 6-monthly review having had her routine blood tests two weeks prior to her clinic visit. She has diagnosed with HIV seven years ago and has been stable on antiretroviral therapy since then. Her other medical problems include asthma which is well controlled. She reports generally good compliance with her medications but has unfortunately missed two of her treatment doses as she was on a weekend holiday and forgot to take her tablets with her. She feels well in herself.

Blood tests:

	Today	Two weeks ago	One year ago
HIV viral load	110 copies/ml	<50 copies/ml	<50 copies/ml
CD4 count	983 cells/mm ³	912 cells/mm ³	Not tested

How should she be further investigated?

	Urgent CD4 count
	Urgent viral resistance testing
	Urgent HIV-1 and HIV-2 serology
	Repeat viral load in one month
	Routine viral load and CD4 count in six months

Dashboard

Overall score: 0%

□ Question 33 of 155

A 42-year-old woman presents to the emergency department with a dry cough. Over the last five days, she has been suffering from a worsening dry cough, shortness of breath that is worse on exertion, and she has felt hot. She has a past medical history of HIV which was recently diagnosed, but no other medical problems. She has been started two months ago on antiretroviral treatment and PCP prophylaxis, to which she reports good compliance.

Fundoscopy shows white branches alongside blood vessels. She denies any eye pain or change in her vision.

Observations:

Saturations	93%
Respiratory rate	20/min
Blood pressure	131/70mmHg
Heart rate	89/min
Temperature	38.1°C

Blood tests:

Hb	122 g/l
Platelets	401 * 10 ⁹ /l
WBC	10.2 * 10 ⁹ /l
Na ⁺	138 mmol/l
K ⁺	4.2 mmol/l
Urea	5.1 mmol/l
Creatinine	71 µmol/l
HIV viral load	12,198 copies/ml
CD4 count	70 cells/mm ³

A chest X-ray shows bilateral interstitial infiltrates. A broncho-alveolar lavage is organised but shows no organisms on microscopy, including with silver staining. PCR studies are pending.

What is the most appropriate treatment?

	Prednisolone
	Low-molecular weight heparin
	Tazocin
	IV co-trimoxazole
	Ganciclovir

Dashboard

Overall score: 0%

□ Question 34 of 155

A 38 year old ex-intravenous drug user attends the GUM clinic for review. He describes a history of needle sharing in the past and is no longer abusing intravenous drugs. He also describes unprotected sexual intercourse with a number of partners who he no longer is in touch with, most recently 3 days prior to attending clinic. He has come to clinic after hearing a recent awareness campaign around the dangers of undiagnosed hepatitis C. He is currently well and cannot recall ever being jaundiced.

He has a wide range of investigations as detailed below.

Hepatitis B core antibody (HBcAb) - positive
Hepatitis C antibodies - positive
HIV antibody negative
p24 antigen negative

Further testing was carried out based on the results above

Hepatitis B surface antigen (HbsAg) negative
Hepatitis B surface antibody (HbsAb) positive
Hepatitis B envelope antigen (HbeAg) negative
Hepatitis C RNA - negative

What is the most accurate profile of the patient detailed above?

	HIV negative, Hepatitis B chronic carrier, Hepatitis C chronic infection
	HIV negative, Hepatitis B chronic carrier, Hepatitis C active infection
	HIV negative, Hepatitis B active infection, Hepatitis C spontaneously cleared
	HIV negative, Hepatitis B previous infection, Hepatitis C spontaneously cleared
	HIV negative, Hepatitis B previous infection, Hepatitis C chronic infection

Overall score: **0%**

□ Question 35 of 155

A 27-year-old male presents with high-grade fever and vomiting for 8 days. He recently went to Africa for a jungle safari with a group of friends and began feeling unwell whilst he was there. During the trip, he spent most of the time camping outdoors. He does not have any history of fits or loss of consciousness, although he has been feeling drowsy and complains of generalised malaise. He also has pain in his wrist and shoulder joints but they are not swollen. He takes alcohol regularly and smokes cannabis socially.

On examination, he has a fever of 39°C and a pulse of 135bpm. His blood pressure is 100/70mmHg. He is icteric but does not have any flapping tremors. There is evidence of an enlarged spleen which is palpable 3 finger breadths below the left costal margin. The liver span is normal.

Lab reports reveal:

Hb	115 g/l
Platelets	100 * 10 ⁹ /l
WBC	9.5 * 10 ⁹ /l
Reticulocytes	5% (0.2 - 2%)

Na ⁺	140 mmol/l
K ⁺	4.6 mmol/l
Urea	5.1 mmol/l
Creatinine	83 µmol/l

Bilirubin	49 µmol/l
AST	50 u/l
ALT	25 u/l
Glucose	6.0 mmol/l

CT scan brain: Normal

CSF examination reveals:

Appearance	Clear
Protein	0.3 g/L (0.2 0.4 g/L)
Glucose	5.3 mmol/l
Lymphocytes	15/mm ³
Neutrophils	10

Which of the following is the most appropriate treatment option?

	Chloroquine
	Artemether/lumefantrine
	Primaquine
	IV acyclovir
	Co-trimoxazole

Dashboard

Question 36 of 155

□ □

A 17 year old girl presents to A&E accompanied by her anxious mother. She was born in England, but both her parents were born in a rice growing community in rural China. She has recently returned from a holiday where she was visiting her family in China. They live on a farm where she had close contact with dogs, sheep and pigs. She arrived home one week ago. She was taking Mefloquine for malaria prophylaxis.

She was complaining of fever and a headache yesterday. Today she has been confused and disorientated.

She is previously fit and well, she has had all her immunisations according to the UK immunisation schedule, with normal growth and development. She does well at college and is a keen member of her college canoe club. She has no allergies.

On examination she is febrile at 38.9°C but haemodynamically stable. She appears confused and has an obvious difficulty walking. Examination of her cranial nerves is difficult but unremarkable. She has normal power and increased tone in her arms, which is more pronounced on the left side, with hyperreflexia bilaterally. She has several writhing involuntary movements of her upper limbs during the consultation.

A CT scan shows hypodensity in the thalami and basal ganglia bilaterally, more pronounced on the left side.

A lumbar puncture reveals a lymphocytic CSF with a raised protein.

What is the most likely diagnosis?

	Herpes Simplex Encephalitis
	Japanese Encephalitis
	Alcohol consumption
	Rabies
	Mefloquine toxicity

Overall score: **0%**

□ Question 37 of 155

□ □

A 22-year-old man presented to his General Practitioner with an itchy rash across his arms and legs. Symptoms had developed within the last few days and were causing the patient significant discomfort and preventing him from sleeping. The patient was a university student currently enjoying his summer vacation. He reported returning from a backpacking trip around Eastern Europe one week previously when he had stayed mostly in youth hostels. Since his return he had been staying in his parent's home. Interestingly, the patient had discovered on Facebook that a similar rash had afflicted a friend he had made at the end of his holiday.

He also worked part-time as a barman and denied coming into contact with any unusual chemicals at work. He had not recently introduced any new skin care products.

The patient had suffered from mild atopic eczema as an infant but had no recent skin complaints or other past medical history. He took no regular medications and had no known allergies. The patient smoked 10 cigarettes per day and drank roughly 40 units of alcohol each week.

On examination, the patient's arms and legs were covered with 2-5 mm maculopapular lesions with a central haemorrhagic punctum. In several places, several lesions were noted to be lying close together in a curve formation. There were minor marks of excoriation associated with the lesions. The patient's groin, abdomen, chest and back were free from rash. There was no axillary, cervical or inguinal lymphadenopathy.

What organism is the likely cause for the patient's rash?

	<i>Sarcoptes scabiei</i>
	<i>Leishmania donovani</i>
	<i>Ancylostoma braziliense</i>
	<i>Mycobacterium leprae</i>
	<i>Cimex hemipterus</i>

Overall score: **0%**

Question 38 of 155

A 24 year-old student was referred to the Acute Medical Unit by his general practitioner with a 4-week history of increasing cough and breathlessness. The cough was generally non-productive but he had coughed up a small amount of blood on 3 occasions. His past medical history consisted only of asthma which was well controlled with a salbutamol inhaler. There was no family history of venous thromboembolism. His recent travel history included a trip to Sierra Leone 3 months ago. He was a non-smoker and drank 20 units of alcohol per week.

On examination, his temperature was 37.6oC, heart rate 80 beats per minute, blood pressure 124/88 mmHg, respiratory rate 22 breaths per minute and oxygen saturations 92% on room air. He was able to talk in full sentences. A few bibasal crackles were evident on auscultation of the chest. His JVP was not elevated and heart sounds were normal.

Investigations:

Haemoglobin	144 g/L (130-180)
White cell count	$7.0 \times 10^9/l$
Neutrophil count	$3.5 \times 10^9/l$
Lymphocyte count	$1.6 \times 10^9/l$
Eosinophil count	$1.3 \times 10^9/l$
Platelets	$330 \times 10^9/l$

Sodium	138 mmol/L
Potassium	3.9 mmol/L
Urea	7.0 mmol/L
Creatinine	65 mol/L
Alkaline phosphatase	40 IU/L
Alanine aminotransferase	33 IU/L
Gamma-glutyl transferase	18 IU/L

Bilirubin	14 mol/L
Albumin	40 g/L

Chest x-ray: Bilateral lower zone haziness
ECG: Normal sinus rhythm

What is the most appropriate treatment for the underlying condition?

	Mebendazole
	Low molecular weight heparin
	Fluconazole
	Doxycycline
	Artesunate

Dashboard

Question 39 of 155

A 48 year-old civil servant was referred to the Acute Medical Unit by his general practitioner with progressive cognitive impairment and severe lethargy over the last 3 weeks. He had also become intermittently agitated and his sleep was disturbed during the night. He had returned from visiting his partners relatives in Zimbabwe 1 month ago. He suffered from type II diabetes which was well controlled through dietary modification. He smoked 10 cigarettes a day and drank 14 units of alcohol per week.

On examination, his temperature was 37.2°C, pulse was 60 beats per minute and blood pressure was 134/88. His Glasgow Coma Score was 14/15 due to confused speech. His trachea was central and right-sided posterior cervical lymphadenopathy was present. His jugular venous pressure was not elevated and chest was clear on auscultation. Heart sounds were normal.

Investigations:

Haemoglobin	143 g/L (130-180)
White cell count	7.7 x 10 ⁹ /L (4.0-11.0)
Neutrophil count	3.0 x 10 ⁹ /L (2.0-7.5)
Lymphocyte count	1.8 x 10 ⁹ /L (1.3-3.5)
Eosinophil count	0.4 X 10 ⁹ /L (0.1-0.4)
Platelets	310 x 10 ⁹ /L (150-400)

Sodium	134 mmol/L (135-145)
Potassium	4.8 mmol/L (3.5-5.0)
Urea	9.0 mmol/L (2.5-7.5)
Creatinine	100 mol/L (25-95)
Fasting plasma glucose	4.4 mmol/L (3.0-6.0)

CT head	No abnormality detected
---------	-------------------------

What is the most appropriate next investigation?

	MRI brain
	Lymph node biopsy
	Lumbar puncture
	Stool microscopy

Question 40 of 155

□ □

A 37-year-old man is referred to the medical outpatient clinic. He was born in Brazil but has been in the UK since university and now works in marketing.

He has been complaining of increasing breathlessness, worse on exertion, and is now breathless on climbing a flight of stairs. He has had several faints in the last few months, associated with feeling a 'funny' sensation in his chest, following which he blacks out. On one occasion he sustained a cut on his eye brow. There are no triggers to these episodes and there is a rapid recovery. He has never had any episodes of incontinence or tongue biting.

His past medical history is unremarkable. He was treated with several courses of antibiotics as a child in Brazil for an eye infection that persisted for several months. He has been seeing his GP for the past year for increasingly troublesome constipation. His medications are:

Senna 15mg at night
Movicol two sachets tds

On examination he has a displaced apex beat, normal heart sounds, and mild coarse crepitations at both lung bases.

What is the likely diagnosis?

	Chagas disease
	Endomyocardial fibrosis
	Churg Strauss Syndrome
	Hypertrophic Obstructive Cardiomyopathy
	Vasovagal syncope

Overall score: **0%**

Question 41 of 155

□ □

A 65 year-old gentleman with type 2 diabetes mellitus and alcoholism presents with fever, headache and neck stiffness. He has a history of previous anaphylactic reaction to penicillin.

On examination the temperature is 37.9°C, respiratory rate is 20 breaths/min and heart rate is 105 beats per minute. Nutritional state and dental hygiene is poor. The chest is clear to auscultation. The abdomen is soft and non-tender. The Glasgow coma scale score is 15, the patient is uncomfortable during pen-torch pupillary examination and neck flexion is limited by pain.

CSF examination reveals:

White Cells	560 per mm ³ (85% polymorphs)
Red cells	8 per mm ³
Protein	0.9g/L
Glucose	3.3mmol/L (serum glucose 9.2mmol/L)
Gram stain	Gram-negative coccobacilli

Which antimicrobial agent should be initiated?

	Vancomycin
	Ceftriaxone
	Chloramphenicol
	Rifampicin
	Gentamicin

Overall score: **0%**

Question 42 of 155

□ □

A 35-year-old female returned from Tanzania 2 weeks ago. She had consulted her GP after feeling unwell over the previous 3 days with intermittent symptoms of fever, headache and generalised arthralgia. She had taken doxycycline as an antimalarial and denies missing any of the prescribed doses and had been fully vaccinated prior to her travel.

She is referred to the medical take where you retake the history. She admits to getting mosquito bites regularly whilst away, one of them she seemed to react severely to and this has left a mark on her shoulder.

On examination she appears drowsy, she has mild hepatosplenomegally and there is a well circumscribed, rubbery, painful, red lesion approximately 5cm in diameter above her left shoulder.

What is the likely diagnosis?

	<i>Plasmodium falciparum</i>
	<i>Trypanosomiasis brucei rhodesiensi</i>
	<i>Trypanosomiasis brucei cruzi</i>
	<i>Trypanosomiasis brucei gambiensi</i>
	<i>Toxoplasmosis</i>

Question 43 of 155

□ □

A 28-year-old patient has presented with upper limb weakness. He is extremely anxious and tells you that this morning he noticed that he had a dry mouth and found it difficult to swallow. His friends also commented that his voice sounded different to normal. Several hours later he began to notice weakness in both of his arms. He has not noticed any weakness in his lower limbs. He has no relevant past medical history or family history of note. He smokes 10 cigarettes a day, drinks approximately 30 units of alcohol per week and occasionally injects heroin.

His Glasgow Coma Score is 15/15. Neurological examination reveals power 3/5 in the upper limbs, 5/5 in the lower limbs. Biceps and supinator reflexes are absent. Knee and ankle reflexes are normal. His pupils are dilated and sluggish in reaction to light. He is unable to abduct either eye. You notice needle track marks on the patient's forearm and an erythematous wound in the patient's right antecubital fossa.

What is treatment would you give to the patient immediately?

<input type="checkbox"/>	IV Beta Interferon
<input type="checkbox"/>	IV immunoglobulin
<input type="checkbox"/>	Plasma exchange
<input type="checkbox"/>	Steroids
<input type="checkbox"/>	Trivalent antitoxin

A 29-year-old man presents to his first HIV clinic appointment. He has routine three month HIV tests. He received contact tracing notification last week and was tested and found to be HIV positive. He has just started antiretroviral treatment.

At clinic he mentions that he is due to go to South Africa. He hasn't yet had his travel vaccinations and is worried about what affect the new diagnosis of HIV will have on his travel plans. He is aware that currently immunosuppressed and at risk of infections and is committed to taking his tablets.

Investigations:

Haemoglobin	113 g/L (130-180)
White cell count	6.5 10 ⁹ /L (4.0-11.0)
Neutrophil count	5.4 10 ⁹ /L (1.5-7.0)
Platelet count	170 10 ⁹ /L (150-400)
CD4 count	180 cells/mm ³ (600-1500)

Which of the following vaccinations is safe to be given?

<input type="checkbox"/>	Yellow fever
<input type="checkbox"/>	BCG
<input type="checkbox"/>	Oral polio
<input type="checkbox"/>	Meningococcal C
<input type="checkbox"/>	Varicella

□ Question 46 of 155

□ □

A 24 year old Caucasian girl returned from a two week scuba diving holiday in Honduras four days ago. She had not taken malaria prophylaxis. She had been drinking alcohol moderately during her trip. She had unprotected sex during her holiday with her diving instructor.

Yesterday she had felt hot and cold with pain all over her body and a headache. Today the pain is worst behind her eyes. It is a constant pain and there is no photophobia or neck stiffness. She has an erythematous rash over her trunk and back with patches of white skin surrounded by erythema. There is no lymphadenopathy

She is observed in hospital for 48 hours and tests for HIV (including PCR and antibody), malaria and blood cultures were negative. Further tests remain unreported.

She recovers and is feeling much better. Prior to discharge she asks if she is safe to go back to Honduras next year.

What should you advise?

	She should not go back to any Dengue endemic area as there is a risk of Dengue haemorrhagic fever (with a 20% mortality) with a second exposure to Dengue virus
	She can go back to Honduras, although there is a small risk of Dengue haemorrhagic fever with a second exposure, the risk is small enough not to be overly worried. She should take precautions not to be bitten by mosquitos during the day
	She has had Dengue fever so will be immune to Dengue fever on subsequent exposure.
	She has had flu and therefore she can go back to Honduras next year.
	Staying in the UK from now on would be the most sensible given that she is at high risk of malaria, HIV and Dengue fever from her behavioral tendencies.

□ Question 47 of 155

A 55-year-old woman is referred for an urgent assessment by the infectious diseases team after presenting to her local out of hours GP. The patient stated that she was concerned about having caught Lyme disease during a recent day out in the New Forest in Hampshire, UK. The patient was particularly concerned about this diagnosis as she had a close friend who had been forced to give up work after suffering from neuroborreliosis.

On closer questioning, the patient reported that 2 days previously she had gone on a walk in the New Forest. When she had arrived home that evening she had found two engorged ticks attached to her right lower leg. Her husband had removed the ticks by applying nail polish to them and then pulling them off with tweezers.

The patient denied suffering from any symptoms at the time of presentation though admitted she was very anxious. In particular, the patient had not experienced any neurological or cardiovascular symptoms and had not observed any skin rashes.

The patient was receiving treatment from her GP for hypercholesterolaemia and mild asthma. The patient had no known drug allergies and was employed as a legal secretary at a local firm.

A full examination of the patient's skin was performed and no abnormal rashes or other skin changes were identified. No focal neurology was identified on examination of the peripheral and central nervous systems. The assessment did not identify any signs of meningism. The patient was afebrile.

What is the appropriate management of this patient's tick bites?

	Treat with amoxicillin for 14 days
	Immediate serological testing for pathogenic <i>Borrelia</i> species
	Serological testing for pathogenic <i>Borrelia</i> species in 4 weeks (to allow for seroconversion)
	No investigation or treatment indicated at present time, carefully observe for onset of symptoms
	Treat with doxycycline for 14 days

Overall score: **0%**

□ Question 49 of 155

A 28-year-old female presents with a 4-day history of fevers and joint pain. She has recently returned from a 3 month gap year trip to the South-East Asia three days ago and reports no ill health during her travels. She has no past medical history, does not smoke, drinks minimal alcohol and denies the use of illicit drugs. During her travels, she reports two episodes of unprotected sexual contact with a non-regular partner. Although she knew she would be entering a malaria area and was indeed bitten by mosquitoes on a number of occasions, she did not take any malaria prophylaxis.

On examination, heart sounds and chest examination are both normal. A maculopapular rash is noted on her left thigh and right upper arm, with bilateral conjunctival injection. Abdominal examination reveals a soft abdomen with no masses. She has a significantly joint and muscle pains, limiting your neurological examination. She is alert and orientated to time and place, scoring 10/10 on abbreviated mental testing. Her blood tests are as follows:

Hb	109 g/l
Platelets	$45 \times 10^9/l$
WBC	$3.5 \times 10^9/l$

Na ⁺	137 mmol/l
K ⁺	3.8 mmol/l
Urea	7.1 mmol/l
Creatinine	100 μ mol/l
CRP	70 mg/l

Bilirubin	7 μ mol/l
ALP	30 u/l
ALT	162 u/l

Her first malaria film is negative and a chest radiograph is unremarkable.

What is the most likely diagnosis?

	Gonorrhoea with reactive arthritis
	HIV seroconversion
	Dengue fever
	Malaria falciparum
	Typhoid

□ Question 51 of 155

A 22-year-old man is brought to the emergency department after being granted asylum in the UK. Immigration officials had been concerned about the patient's well-being immediately on his arrival in the country. The patient reported feeling progressively more unwell over the previous 3 months after he had fled from his village in Syria. The primary symptoms reported by the patient were fevers, severe night sweats and profound fatigue. In addition, the patient had found that his exercise tolerance has greatly reduced in the previous four weeks and he became markedly breathless on minimal exertion.

The patient explained that he had experienced a prolonged period of inadequate food and shelter due to the war in his home country and while travelling across Europe. The patient had previously lived in a small village in Syria and had worked as a sheep farmer. Prior to fleeing his home the patient had regularly consumed food products made with unpasteurised sheep's milk. The patient had previously been in good physical health and had suffered no significant medical problems during his life.

On general examination, the patient appeared unwell and diaphoretic. The patient's sweat was noted to have an unusually unpleasant odour. Examination of the cardiovascular system identified multiple splinter haemorrhages under the patient's fingernails and toenails. Jugular venous pressure was elevated by 3-4 cm and pitting oedema was present to the patient's knees. A harsh systolic murmur was heard over the aortic area on auscultation. Bilateral basal crackles were heard on auscultation of the patient's lungs. The patient's spleen was palpable on examination of the abdominal system. No palpable lymphadenopathy was identified.

Please see the below table for results of initial investigations.

Haemoglobin	123 g / dL
Mean cell volume	80.3 fl
Lymphocytes	4.9×10^3 / microlitre (reference 1.5-4.0)
Platelets	109×10^3 / microlitre
Urea	8.9 mmol / L
Creatinine	126 micromols / L
Sodium	137 mmol / L

Potassium	4.1 mmol / L
Erythrocyte sedimentation rate	102 mm / h (reference 0-35)
C-reactive protein	99 mg / L (reference < 7)
Urinalysis	Positive for blood + + +
Chest x-ray	Upper lobe blood diversion; generalised patchy airspace shadowing; bilateral shallow pleural effusions
ECG	Sinus rhythm; borderline right bundle branch block
Focused bedside transthoracic echocardiogram	0.6 cm vegetation on aortic valve; evidence of moderate-severe aortic stenosis; ejection fraction 30 %

Which of the following organisms is the most likely cause of the patient's presentation?

<input type="radio"/>	<i>Clostridium burnetti</i>
<input type="radio"/>	<i>Bartonella quintana</i>

□ Question 52 of 155

A 55 year old man attended his General Practitioner to complain of on-going fatigue and lethargy over recent months. He reported experiencing recurrent minor infections meaning that he had rarely been feeling well for any significant length of time. His GP records supported this story with the patient having been prescribed courses of antibiotics for a leg cellulitis, suppurative otitis media and sinusitis (twice) over the past 9 months. The patient reported a good appetite and no recent weight loss, fevers or night sweats. He denied any symptoms of arthritis, skin rashes, photophobia or dry eyes. There were no significant gastrointestinal or genitourinary symptoms.

Past medical history included obesity, hypertension, impaired fasting glucose tolerance and osteoarthritis of the knees. Drug therapy included ramipril 2.5 mg daily, bendroflumethiazide 2.5 mg daily and paracetamol as required. The patient was divorced with two grown up children. He was an ex-smoker who rarely drank alcohol. The patient had recently retired having previously worked as a salesperson for luxury yachts, an occupation that had involved extensive travel around the world.

On examination, the patient was significantly overweight (BMI 36 kg / m²). Abdominal examination did not demonstrate any jaundice or signs of chronic liver disease and no lymphadenopathy. Cardiovascular, respiratory and musculoskeletal examination was unremarkable. Given the patients concerns, his General Practitioner arranged some basic blood tests.

Haemoglobin	16.0 g / dL
Mean cell volume	85 fL
White cell count	5.2 * 10 ⁹ /l
Neutrophils	4.2 * 10 ⁹ /l
Lymphocytes	0.6 * 10 ⁹ /l

□ Question 52 of 155

A 55 year old man attended his General Practitioner to complain of on-going fatigue and lethargy over recent months. He reported experiencing recurrent minor infections meaning that he had rarely been feeling well for any significant length of time. His GP records supported this story with the patient having been prescribed courses of antibiotics for a leg cellulitis, suppurative otitis media and sinusitis (twice) over the past 9 months. The patient reported a good appetite and no recent weight loss, fevers or night sweats. He denied any symptoms of arthritis, skin rashes, photophobia or dry eyes. There were no significant gastrointestinal or genitourinary symptoms.

Past medical history included obesity, hypertension, impaired fasting glucose tolerance and osteoarthritis of the knees. Drug therapy included ramipril 2.5 mg daily, bendroflumethiazide 2.5 mg daily and paracetamol as required. The patient was divorced with two grown up children. He was an ex-smoker who rarely drank alcohol. The patient had recently retired having previously worked as a salesperson for luxury yachts, an occupation that had involved extensive travel around the world.

On examination, the patient was significantly overweight (BMI 36 kg / m²). Abdominal examination did not demonstrate any jaundice or signs of chronic liver disease and no lymphadenopathy. Cardiovascular, respiratory and musculoskeletal examination was unremarkable. Given the patients concerns, his General Practitioner arranged some basic blood tests.

Haemoglobin	16.0 g / dL
Mean cell volume	85 fL
White cell count	5.2 * 10 ⁹ /l
Neutrophils	4.2 * 10 ⁹ /l
Lymphocytes	0.6 * 10 ⁹ /l
Monocytes	0.1 * 10 ⁹ /l
Eosinophils	0.1 * 10 ⁹ /l
Basophils	0.2 * 10 ⁹ /l
Platelets	358 * 10 ⁹ /l
Urea	6.8 mmol / L

Creatinine	110 micromol / L
Sodium	141 mmol / L
Potassium	3.9 mmol / L
Albumin	34 g / L (reference 35-50)
Alkaline phosphatase	98 U / L (reference (35-100)

Question 53 of 155

You see a 26-year-old Caucasian man with poorly controlled HIV (recent CD4 count of 113 cells/mm³) with a negative Mantoux test. He was routinely tested after his father (whom he lives with) was diagnosed with active pulmonary disease, but himself shows no features of active disease. On examination, his chest is clear with no overt lymphadenopathy. Blood pressure is 132/91 mmHg, heart rate 85 beats per minute, respiratory rate 14 breaths per minute, oxygen saturation 96% on air and temperature 36.8°C.

What is the next step?

	5 days oral ciprofloxacin
	QuantiFERON-TB (interferon gamma assay)
	Induced sputum for AAFB
	Monitor and repeat Mantoux in 2 weeks
	Rifampicin and isoniazide for 6 months with pyrazinamide and ethambutol for 2 months

□ Question 54 of 155

A 40-year-old gentleman was admitted with fever, dry cough, headache, abdominal pain and diarrhoea. Around ten days previously he had been complaining of intermittent fevers and night sweats but otherwise felt well. In the last 3 days, he had developed generalised abdominal pain and watery diarrhoea, along with a dry cough and headache. Prior to this he had felt constipated only having opened his bowels once in three days which he thought was unusual as he had eaten a large amount of fruit off the market stools in South Korea where he had recently been on a business trip.

On examination, he was notably jaundiced, had a macular rash over his chest and had tender hepatomegaly. Observations revealed a temperature of 40.1°C, heart rate 38/min, regular and a blood pressure of 130/90 mmHg. ECG showed a sinus bradycardia.

Blood tests revealed:

WBC	14.0 * 10 ⁹ /l
Neutrophils	12.0 * 10 ⁹ /l
CRP	230 mg/l
Bilirubin	52 µmol/l
ALP	80 u/l
ALT	200 u/l
Albumin	32 g/l

What investigation would you do to obtain the diagnosis?

	Blood cultures
	Abdominal ultrasound
	HIV test
	Lumbar puncture

	ECG

Question 58 of 155

□ □

A 38 year old man from Nigerian man presents to a gastroenterology clinic. He is a businessman, working for an iron and steel trading company and makes regular trips to Swaziland to visit mining executives.

For the previous four months he has been troubled by diarrhoea, up to 8 episodes a day, with abdominal bloating and cramping. There is no blood visible in the stool. He has previously been treated for tuberculosis as a child.

A stool sample is sent to the lab, and Modified Ziehl-Neelson stain reveals multiple red staining round objects measuring 5 microns in diameter.

What will be the most appropriate treatment?

	Highly active anti-retroviral therapy
	Co-trimoxazole
	Rifampicin, isoniazid, ethambutol, pyrazinamide
	Metronidazole
	Ciprofloxacin

Question 59 of 155

A 35-year-old man is brought into the Emergency Department after 3 successive tonic-clonic seizures. He was given 10mg of rectal diazepam and has since stabilised.

A brief history from his girlfriend states that he was usually fit and well apparent from recurrent sinusitis. Over the past month, however, he had been complaining of increasing headaches and had received a course of antibiotics from his GP.

He takes no regular medication but his partner states that they do occasionally take ecstasy whilst on nights out.

On examination, he is drowsy with a Glasgow Coma Scale (GCS) of 12. His temperature is 38.8 degrees Celsius, his pulse is 57 bpm and regular, blood pressure 150/90 mmHg, oxygen saturations 97% on 15L oxygen via a non-rebreathe mask.

Cardiovascular examination reveals normal heart sounds, capillary refill time of 3 seconds. His calves were soft and non-tender. His chest was clear with no signs of consolidation. Abdominal examination was unremarkable.

Neurological examination was difficult in view of the patients low GCS but no focal abnormality could be detected. On attempt to passively flex his neck he became agitated and obviously uncomfortable. Pupils were equal and reactive to light. Fundoscopy demonstrated bilateral oedematous optic discs.

Bloods were as follows:

Na+	130 mmol/L
K+	3.9 mmol/L
Urea	5 mmol/L
Creatinine	80 μ mol/L
Hb	160 g/L
WBC	$25.0 \times 10^9/L$
Neutrophils	91%

LFTs	Normal
CRP	90 mg/L

Based on the findings above, what is the most likely diagnosis?

	Intracerebral abscess
	Sepsis secondary to sinusitis
	Ecstasy overdose
	Meningitis
	Cerebral lymphoma

Question 60 of 155

□ □

A 36 year old male Intravenous drug user presents to genito-urinary clinic. He was diagnosed with HIV 3 years ago after presenting with tuberculosis (TB). He was treated for TB for 6 months. He is now on third line anti-retroviral therapy for previous virological failure and co-trimoxazole. His most recent CD4 count was 104, and his viral load was 3,000 copies/ml.

He complains of weakness on his left side, and deterioration in vision, getting worse for four weeks. He has a moderately severe headache. On examination his visual acuity is 3/60 in his left eye and 6/6 in his right eye. He has weakness, in his left arm and leg, brisk reflexes and mildly increased tone.

He is immediately admitted.

A CT scan shows several ring enhancing lesions in his right cerebral hemispheres and one on the left cerebral hemisphere.

On ophthalmological review he has a large area of retinal necrosis in his left eye.

What is the diagnosis?

	CNS lymphoma
	Cerebral toxoplasmosis
	Cerebral TB
	Cerebral abscesses
	CNS Kaposi sarcoma

Question 62 of 155

A returning traveller presents to the emergency department with a 10 day history of fever, cough and abdominal pain. He has spent the last 2 weeks in Jakarta, Indonesia. His vital signs are: temperature: 40.1°C, heart rate 85 beats/minute, blood pressure 120/80 mmHg

On examination his spleen is enlarged and there is a rose spot rash over the chest. Blood culture grows salmonella typhi and the on-call doctor diagnoses enteric fever (typhoid).

If left untreated, what is the most important and serious complication that can occur within the following 2 weeks?

<input type="checkbox"/>	Chronic carriage within gallbladder
<input type="checkbox"/>	Bowel perforation and haemorrhage
<input type="checkbox"/>	Splenic infarction and rupture
<input type="checkbox"/>	Acute liver failure
<input type="checkbox"/>	Bacterial meningitis

□ Question 64 of 155

A 54 year old Caucasian man with HIV, is stable on Tenofovir, Emtricitabine and Kaletra (Lopinavir/Ritonavir). He has a 60 pack year smoking history and has been told his blood pressure is high previously but had never previously been to see his GP about it to get it treated. His GP is unaware of his HIV diagnosis and his main point of healthcare contact is with the Genito-urinary medicine services.

However over the last two years he has been troubled by gradually worsening cough, and shortness of breath. He has not lost weight. This has spurred him to start seeing his GP. He says that his GP initially gave him a blue inhaler and did some tests and told him he had COPD. Six weeks ago his GP gave him a Seretide 500 inhaler (one puff twice a day) and started him on Rampril (2.5mg daily) for his high blood pressure. The purple inhaler had provided some relief to his breathlessness but four days ago it ran out and he hasn't yet been back to see his GP. He still has two weeks worth of Ramipril tablets.

For the last few days he has been feeling faint and dizzy especially when standing up. His breathlessness and cough are no worse than usual. He has no fever. On examination his blood pressure is 91/76 his pulse is 94. He is afebrile, his respiratory rate is 24 and his oxygen saturations are 92% on room air. He has a mild wheeze on auscultation of his chest. His heart sounds are faint and his JVP is visible 3cm above his sternal angle. There is no pitting odema. There is nothing else of note on examination.

An ECG on admission is normal.

Hb	14.0 g/dl
Platelets	$199 \times 10^9/l$
WBC	$6.2 \times 10^9/l$

Na ⁺	130 mmol/l
K ⁺	5.9 mmol/l
Urea	5.6 mmol/l
Creatinine	85 μ mol/l
CRP	7 mg/l

What is the diagnosis?

	Adrenal tuberculosis
	Pericardial tuberculosis
	Adrenal insufficiency secondary to inhaled corticosteroid withdrawal
	Ramipril induced hypotension
	WaterhouseFriderichsen syndrome

Question 65 of 155

A 36-year-old gentleman was admitted to the Medical Admission Unit. His principle complaint was watery diarrhoea which has been present for the last few weeks. He had not noticed the presence of blood or mucus in the stool. He also complained of transient pain on swallowing, and weight loss of 2 stones over the last year. He denied the presence of respiratory symptoms and abdominal pain. He had no past medical history of note from his GP records. He consumes 20 cans of standard strength lager per week, smokes 20 cigarettes per day and denies recreational drug use. He had no fixed abode.

On examination, he was unkempt and dishevelled, with a BMI of 17.1 kg/m². Cardiovascular and respiratory examinations were unremarkable except for an oxygen saturation of 94% on room air. His heart rate was 92/min, blood pressure 112/62 mmHg and temperature 36.7°C. Abdominal examination was also unremarkable though examination of the oral cavity revealed the presence of multiple aphthous ulcers. Examination of the neck revealed multiple small palpable cervical lymph nodes. Fundoscopy revealed the presence of white patches but otherwise, nil else and central and peripheral nervous system examination was otherwise normal. Skin examination revealed multiple pearly pink umbilicated nodules.

Initial investigations revealed the following:

Hb	122 g/l
Platelets	189 * 10 ⁹ /l
WBC	3.6 * 10 ⁹ /l

Chest x-ray: normal appearances of the heart and chest

ECG: 92bpm normal sinus rhythm, no other abnormalities seen

Urinalysis: normal

Stool MCS: normal interim results, pending further analysis

Which is the single investigation most likely to lead to the underlying diagnosis?

	CT head, chest, abdomen and pelvis
	Upper gastrointestinal endoscopy

	Bone marrow biopsy
	Colonoscopy
	HIV serology

□ Question 66 of 155

A 45 year old man with mild learning difficulties and newly diagnosed advanced HIV (CD4 count 65 /mm³) attends A&E from his residential home. He has an intensely itchy rash on his hands, arms, groin, legs and feet. He was recently commenced on Atripla (Emtricitabine, Tenofovir, Efavirenz) and co-trimoxazole.

© Image used on license from DermNet NZ

There is extensive crusted scaling on his arms, groins and hands. On closer examination there are grey burrow marks between the webs of his fingers and toes. There are itchy nodules extensively over the palms and backs of his hands.

What is the most appropriate treatment?

	Isolate and apply topical malathion cream for 24 hours
	Isolate and stop co-trimoxazole
	Discharge with topical steroids
	Change his antiretroviral therapy to a second line regimen
	Isolate and give ivermectin orally

□ Question 67 of 155

A 48-year-old woman originally from South Africa has lived in the UK for 17 years and works as a librarian. She was diagnosed with HIV 18 months ago after she discovered her husband had been having an affair. Her lowest CD4 count was 211 /mm³. She was commenced on Anti-Retroviral Therapy (ART) on diagnosis with Tenofovir, Emtricitabine and Kaletra (Lopinavir/Ritonavir) and Co-trimoxazole.

Her past medical history prior to diagnosis was unremarkable. She has been well on her ART until 3 weeks ago when she was seen in HIV clinic with a 4-week history of a cough and weight loss of 3 kilogrammes.

She had a chest x-ray showing new right apical nodular opacities and had scanty Acid Fast Bacilli on sputum smear microscopy. Her CD4 count was 312 /mm³ with and she was commenced on standard TB therapy with Rifampicin, Isoniazid, Ethambutol and Pyrazinamide, as well as switching Kaletra to Efavirenz.

Today she has been brought into hospital by the Police, she was found naked wandering in her street, accosting passers-by and asking them to help her remove a device planted under her skin by the CIA to monitor her thoughts.

Her observations are within normal limits. She is moderately difficult to examine but there is no focal neurology detectable. She has mildly reduced air entry in her right upper lobe and her examination is otherwise normal.

Results:

Hb	8.1 g/dl
MCV	84 fl
Platelets	86 * 10 ⁹ /l
WBC	4.5 * 10 ⁹ /l

CRP	27 mg/l
ESR	41 mm/hr

Urea & electrolytes, liver function tests and thyroid function tests were normal. A CT head and lumbar puncture were also unremarkable.

What is the cause of her admission?

	TB meningitis
	HIV encephalopathy
	Ethambutol toxicity
	Efavirenz toxicity
	Immune thrombocytopaenic purpura

Question 68 of 155

□ □

A 40-year-old man is stable on warfarin therapy for the treatment of atrial fibrillation. Whilst on a stag party in Spain he develops scrotal pain and itching. Whilst in Spain, he is treated with a course of ciprofloxacin for a presumed urinary tract infection. Two weeks later he develops a hot, red, swollen and painful knee and both elbows become inflamed. On examination in the emergency department you identify localised tenderness of the knee and painful movement in all directions. The knee is red and hot. Both elbows are mildly warm, with painful movement on flexion and extension. His conjunctiva are also red. He is afebrile. Examination of his external genitalia is essentially normal however there is evidence of excoriation around the scrotum.

What is the cause of his knee pain?

	Reactive arthritis
	Still's disease
	Septic arthritis
	Gout
	Haemarthrosis

□ □

A 75-year-old male with a long history of intravenous drug use is admitted with fevers, rigors and back pain. Three sets of blood cultures taken at admission grow positive for gram positive cocci in clusters. He is suspected of having *Staphylococcus aureus* bacteraemia and is commenced on intravenous vancomycin.

Half an hour after the infusion is commenced, he is noted by the nurse to be flushed. On examination, he is noted to have erythema over his neck, face and trunk but denies any significant distress or discomfort.

His observations are as follow: blood pressure 125/70 mmHg, heart rate 85/min, temperature of 36.8°C, respiratory rate of 18/min and oxygen saturation of 98% on room air.

Which of the following is the most appropriate management?

	Stopping the vancomycin infusion, administering 200mg of IV hydrocortisone and informing the patient that he is allergic to the medication
	Stopping the vancomycin infusion and administering a single dose of 0.5mcg intramuscular adrenaline
	Stopping the vancomycin infusion until symptoms resolve and then re-starting a slower rate
	Stopping the vancomycin infusion and prescribing topical 1% hydrocortisone cream to affected areas
	Continuing the vancomycin infusion and administering 1000 ml of 0.9% saline solution over 1 hour

□ Question 72 of 155

A 25-year-old man is seen in the walk-in travellers clinic. He returned from a holiday in Brazil 5 days ago and has a 1 day history of fever, headache and myalgia. He is usually fit and well. He tells you he took regular malaria prophylaxis while away.

On examination he has a heart rate of 110 beats per minute and a blood pressure of 102/72 mmHg. His temperature is 38.1 °C and he has dry mucous membranes. Examination of cardiovascular, respiratory and gastrointestinal systems is unremarkable but he has multiple mosquito bites over his arms and legs.

His blood tests are as follows:

Hb	132 g/l	Na ⁺	144 mmol/l	Bilirubin	8 µmol/l
Platelets	91 * 10 ⁹ /l	K ⁺	3.5 mmol/l	ALP	98 u/l
WBC	13 * 10 ⁹ /l	Urea	9.7 mmol/l	ALT	22 u/l
Neuts	11 * 10 ⁹ /l	Creatinine	111 µmol/l	γGT	14 u/l
Lymphs	0.6 * 10 ⁹ /l	CRP	78 mg/l	Albumin	40 g/l

He is admitted for broad spectrum antibiotics, fluids and analgesia but his fever continues. His malaria films are negative but he has a positive PCR for dengue virus. Antibiotics are stopped but fluids are continued. His fever and headache settle though he does developed some mild ankle oedema.

Which of the following is true regarding his discharge?

	Dengue shock is unlikely to occur after 24 hours post-fever
	Dengue shock is unlikely to occur once platelets improving
	Dengue shock is unlikely to occur once renal function improving
	Platelets above 20 * 10 ⁹ /l are considered safe for discharge

□ Question 72 of 155

A 25-year-old man is seen in the walk-in travellers clinic. He returned from a holiday in Brazil 5 days ago and has a 1 day history of fever, headache and myalgia. He is usually fit and well. He tells you he took regular malaria prophylaxis while away.

On examination he has a heart rate of 110 beats per minute and a blood pressure of 102/72 mmHg. His temperature is 38.1 °C and he has dry mucous membranes. Examination of cardiovascular, respiratory and gastrointestinal systems is unremarkable but he has multiple mosquito bites over his arms and legs.

His blood tests are as follows:

Hb	132 g/l	Na ⁺	144 mmol/l	Bilirubin	8 µmol/l
Platelets	91 * 10 ⁹ /l	K ⁺	3.5 mmol/l	ALP	98 u/l
WBC	13 * 10 ⁹ /l	Urea	9.7 mmol/l	ALT	22 u/l
Neuts	11 * 10 ⁹ /l	Creatinine	111 µmol/l	γGT	14 u/l
Lymphs	0.6 * 10 ⁹ /l	CRP	78 mg/l	Albumin	40 g/l

He is admitted for broad spectrum antibiotics, fluids and analgesia but his fever continues. His malaria films are negative but he has a positive PCR for dengue virus. Antibiotics are stopped but fluids are continued. His fever and headache settle though he does developed some mild ankle oedema.

Which of the following is true regarding his discharge?

	Dengue shock is unlikely to occur after 24 hours post-fever
	Dengue shock is unlikely to occur once platelets improving
	Dengue shock is unlikely to occur once renal function improving
	Platelets above 20 * 10 ⁹ /l are considered safe for discharge

Stable haematocrit is essential for discharge

Question 73 of 155

A 29-year-old lady comes to see you for advice having seen news of the recent Zika virus outbreak. She and her husband are planning on starting a family, but she has only arrived back from Brazil last week after a business trip. She has not experienced any fever or worrying symptoms, either during travel or since arrival back in the UK. What would be the most appropriate advice to give her?

<input type="radio"/>	Start 5mg folic acid daily
<input type="radio"/>	If no fever can become pregnant
<input type="radio"/>	Need to check Zika virus serology before becoming pregnant
<input type="radio"/>	Should avoid becoming pregnant for at least 2 weeks after travel
<input type="radio"/>	Should avoid becoming pregnant for at least 8 weeks after travel

□ Question 74 of 155

□ □

A 26-year-old woman attends the emergency department requesting treatment following being scratched by a cat two days previously. She had been on holiday with family in Sri Lanka and had been playing with an apparently normal cat who came up to her in the street. Unfortunately, the cat had then scratched her on the forearm and hand, although she insisted that her wounds had only been superficial with no bleeding or broken skin. A relative (a doctor at the local hospital) had subsequently caught the cat and has been holding it in quarantine at his home. The patient had then returned to the UK so as to not miss her flight but on the advice of her relative was requesting treatment for a possible rabies exposure.

The patient's past medical history was significant only for tibial plateau fracture sustained in a sporting accident five years previously. She did not take any regular medications and denied any allergies. She did not recall ever having had a previous course of rabies vaccination.

Examination of the patient demonstrated multiple superficial scratches to her left arm that appeared to be healing normally. There were no areas of broken skin or areas consistent with bite marks. The patient was fully oriented with normal cranial nerve and peripheral nervous examinations. Basic observations were within physiological limits.

What is the correct rabies post-exposure prophylaxis for this patient?

	No action required
	Full course rabies vaccination
	Full course rabies vaccination, stopped if quarantined cat is healthy 10 days after exposure
	Full course rabies vaccination and rabies immunoglobulin
	Full course rabies vaccination if quarantined cat shows signs of rabies within 10 days of exposure

A 26-year-old woman presents to the Emergency Department with a one week history of cough, fever and headache. She returned from Indonesia one week ago.

On examination she appears drowsy and a little muddled. She has no photophobia or focal neurological deficit. She has mild hepatosplenomegaly but no palpable lymphadenopathy. Her chest is clear and heart sounds are normal. She has a macular rash on both legs with a greyish-black scab-like lesion on her left shin.

Investigations results:

Chest x-ray: Bilateral patchy consolidation

Blood culture: Pending

Hb	120 g/l
Platelets	$130 \times 10^9/l$
WBC	$18 \times 10^9/l$
Blood film	Left shifted neutrophils in large numbers

Na ⁺	142 mmol/l
K ⁺	4.1 mmol/l
Urea	6 mmol/l
Creatinine	90 μ mol/l

Bilirubin	23 μ mol/l
ALP	170 u/l
ALT	50 u/l
Albumin	35 g/l

What is the most appropriate first line treatment?

	Azithromycin
	Chloroquine
	Doxycycline
	Mefloquine
	Supportive medications

A 28-year-old man who has recently immigrated from Nigeria presents with a penile ulcer. He reports that it initially started as a small lump but then later progressed to a painful ulcer.

On examination, there is a 7mm diameter tender single ulcer with an undermined ragged edge just proximal to the glans of the penis. Examination of the testes and anal region is unremarkable. There is tender inguinal lymphadenopathy.

What is the most likely diagnosis?

	Syphilis
	Herpes simplex virus
	Granuloma inguinale
	Lymphogranuloma venereum
	Chancroid

Question 77 of 155

□ □

You see Mr Smith, a 35-year-old man-who-has-sex-with-men (MSM) in clinic. He was diagnosed with HIV 5 years ago, commencing combination antiretroviral therapy (cART). Following a number of alterations to his cART due to side effects he responded well to a combination of tenofovir, emtricitabine and ritonavir boosted atazanavir. His plasma viral load (pVL) of HIV RNA has remained undetectable and his adherence has been good.

In clinic today Mr Smith reports 5 weeks of drenching night sweats, a dry cough and some subjective weight loss, going up a belt buckle during this time period. On examination you note that he appears pale and auscultation of the chest elicits crepitations in the left upper zone. You perform a chest X-ray which demonstrates a cavitating lesion in the left upper lobe. You arrange induced sputum samples which confirm a diagnosis of pulmonary tuberculosis.

You explain your diagnosis to Mr Smith and the need to urgently commence him on anti-tuberculosis chemotherapy. Whilst he is happy to commence treatment, he is adamant that he does not want to risk his viral control and states that he is not willing to consider altering his cART regime at present.

What is the most appropriate management step to treat Mr Smith?

	Hold his ART
	Commence rifabutin, isoniazid, ethambutol and pyrazinamide
	Commence isoniazid monotherapy
	Switch protease inhibitor to a novel ARV agent
	Commence rifampicin, isoniazid, pyrazinamide and ethambutol

□ □

A 42-year-old male from Bolivia presents with a 8 month history of progressive fatigue, dyspnoea and intermittent chest pains. He is a chronic smoker and during a recent severe episode of breathlessness had consulted his GP who prescribed amoxicillin and prednisolone to combine with his regular inhaler therapy. Shortly after this he experienced a febrile episode which had lasted 7 days before resolving. His breathlessness also worsened during this period.

On examination he has a temperature of 37.2 degrees, a heart rate of 98 beats per minute, a blood pressure of 110/70 mmHg and a respiratory rate of 24/min. His jugular venous pressure was raised, there was lower limb oedema to the mid shin and a pan systolic murmur heard best in inspiration in the left parasternal region. An ECG showed a prolonged PR interval.

What is the most likely underlying diagnosis?

	Ischaemic heart disease
	Chronic pulmonary emboli
	Chronic Chagas cardiomyopathy
	Sarcoidosis
	HIV

□ Question 82 of 155

A 63 year old man, originally from Ukraine is admitted to hospital with a right sided pleural effusion. On admission he is febrile at 37.8 C. He reports 6kg of weight loss, and night sweats over the previous 4 months.

His pleural effusion is exudative with a pH of 7.4.

A CT chest/abdo/pelvis reveals a right sided pleural effusion, multiple enlarged lymph nodes in his abdomen and mediastinum. A pleural biopsy reveals scanty Acid Fast Bacilli and he is commenced on treatment for tuberculosis with Rifampicin, Isoniazid, Ethambutol, Pyrazinamide. PCR confirms this to be Mycobacterial Tuberculosis complex with wild type rpoB, katG, inhA genes. His HIV serology is positive and his CD4 count is 47 cells/mm³

One week following admission he is commenced on anti-retroviral treatment with Emtricitabine, Lamivudine and Efavirenz with Co-trimoxazole.

Three weeks later he becomes more unwell. He has daily fevers up to 39°C.

On examination he is febrile 38.1 with an associated tachycardia of 119 beats/min, his blood pressure is 112/67 mmHg and respiratory rate is 22 breaths/min. His oxygen saturations are 93%. He has reduced air entry at the right base, but no other abnormality on examinations.

His results are as following:

Hb	10.1 g/dl
MCV	82 fl
Platelets	97 * 10 ⁹ /l
WBC	7.8 * 10 ⁹ /l
Neutrophils	6.3 * 10 ⁹ /l
Lymphocytes	1.2 * 10 ⁹ /l
Eosinophils	0.02 * 10 ⁹ /l

ESR	62 mm/hr
-----	----------

Bilirubin	9 µmol/l
ALP	312 u/l
ALT	153 u/l
γGT	456 u/l
Albumin	22 g/l
CRP	67 mg/l
Lactate	1.1 mmol/l

Other results were as follows;

Urea and electrolytes: normal.
Clotting screen: normal
Blood cultures: negative (x3)
Urinalysis: normal
ECHO: normal
CXR: right pleural effusion
USS abdo: several abdominal nodes visible, nil else.
Toxoplasmosis serology: negative
CMV: IgG negative IgM: negative
EBV: IgG positive IgM: negative
Cryptococcal antigen: Negative
Leishmania serology: negative

What is the most likely diagnosis?

	Pneumococcal pneumonia
	Drug resistant tuberculosis
	Infectious mononucleosis
	Immune reconstitution inflammatory syndrome
	Burkitts Lymphoma

Question 83 of 155

□ □

A 24 year old Somali woman attends her booking appointment in the UK for her first pregnancy. Screening tests reveal that she is HIV positive. She is asymptomatic.

Her viral load is 150 000 copies/ml and her CD4 count is 523 cells/mm³. No viral resistance is detected. Her hepatitis serology is negative. Her husband consequently tests negative for HIV.

She is commenced on triple anti-retroviral therapy (ART) with zidovudine, lamivudine and lopinavir/ritonavir. By 36 weeks her viral load is undetectable at <20 copies/ml.

Which of the following statements is true regarding her ongoing management?

	She should have an elective caesarean section and continue to take her ART whilst breast-feeding.
	She should have a vaginal delivery and continue to take ART whilst breast feeding.
	She should have an elective caesarean section. ART should be continued.
	She should have a vaginal delivery and formula feed. ART can be discontinued.
	She should have a vaginal delivery and formula feed. ART should be continued.

□ Question 85 of 155

A 73-year-old male presents with a three-day history of a productive cough and shortness of breath, and for the last 3 hours he has been confused. His wife tells you that he has been coughing up large volumes of green sputum for the last two hours. He is known to have metastatic prostate cancer and receives regular hormone injections along with his regular medications which are ramipril, simvastatin and aspirin. His temperature is 38.1°C, respiratory rate 24/min, heart rate 115/min and blood pressure 88/45 mmHg. He is dyspnoeic and agitated. There are some crepitations in his right lung field. Heart sounds are normal and his jugular venous pressure is not visible.

Bloods today show:

Hb	151 g/l
Platelets	654 * 10 ⁹ /l
WBC	17.1 * 10 ⁹ /l

Na ⁺	141 mmol/l
K ⁺	3.5 mmol/l
Creatinine	90 µmol/l
CRP	167 mg/l

Bilirubin	16 µmol/l

□ Question 85 of 155

A 73-year-old male presents with a three-day history of a productive cough and shortness of breath, and for the last 3 hours he has been confused. His wife tells you that he has been coughing up large volumes of green sputum for the last two hours. He is known to have metastatic prostate cancer and receives regular hormone injections along with his regular medications which are ramipril, simvastatin and aspirin. His temperature is 38.1°C, respiratory rate 24/min, heart rate 115/min and blood pressure 88/45 mmHg. He is dyspnoeic and agitated. There are some crepitations in his right lung field. Heart sounds are normal and his jugular venous pressure is not visible.

Bloods today show:

Hb	151 g/l
Platelets	654 * 10 ⁹ /l
WBC	17.1 * 10 ⁹ /l

Na ⁺	141 mmol/l
K ⁺	3.5 mmol/l
Creatinine	90 µmol/l
CRP	167 mg/l

Bilirubin	16 µmol/l

□ Question 87 of 155

A 45-year-old female presents with a history of headache and generalised malaise for the last two months. She describes her headaches as being a tight band like sensation which is present almost throughout the day and causes significant difficulty in sleeping at night. She also mentions occasional episodes of vomiting along with low-grade fever and weight loss of about 7 kg over the same duration of time. She suffers from generalised anxiety disorder and takes 0.5mg alprazolam TDS. She returned from Dubai 9 months ago where she had been spending her holidays with her family.

On examination, she has a fever of 37.5°C and a pulse of 105bpm. She appears slightly disoriented with a tendency to speak out of context but is otherwise cooperative.

There is diplopia on right sided gaze and mild neck stiffness, but the remaining clinical examination is essentially unremarkable.

Lab reports reveal:

Hb	115 g/l
Platelets	340 * 10 ⁹ /l
WBC	9.0 * 10 ⁹ /l

Na ⁺	137 mmol/l
K ⁺	4.2 mmol/l
Urea	5.9 mmol/l
Creatinine	102 µmol/l
Glucose	7.0 mmol/l
ESR	87 mm/hr

MRI shows meningeal enhancement but no evidence of any parenchymal lesions.

CSF examination reveals:

Opening Pressure	Normal
Appearance	Turbid
Protein	3.2g/L (0.2 0.4 g/L)
Glucose	2.7 mmol/l
Lymphocytes	371/mm ³
Neutrophils	42/mm ³
ZN staining	No acid fast bacilli detected

Which of the following is the most appropriate treatment option?

	IV acyclovir
	IV ceftriaxone
	Isoniazid, rifampicin, pyrazinamide and dexamethasone
	IV benzylpenicillin
	Artemether/lumefantrine

□ Question 89 of 155

A 22-year-old Ethiopian female presents on the medical take with an exacerbation of asthma. She has been treated for asthma since her late teens and has generally been well controlled with PRN salbutamol alone and has never required steroids or hospital admission.

She became increasingly breathless 3 days ago and visited her GP who prescribed prednisolone and amoxicillin. However her symptoms have worsened considerably and her FEV1 is now 55% her expected value.

On examination she has a temperature of 37.5°C, a heart rate of 92 beats per minute, a blood pressure of 118/76 mmHg and respiratory rate of 22/min. There is diffuse wheeze across across the chest. You also notice excoriations over the skin from intense scratching.

Investigations:

haemoglobin	102 g/L (130-180)
white cell count	5.4 X 10 ⁹ /L (4.0-11.0)
eosinophil count	0.78 X 10 ⁹ /L (0.04-0.40)
platelet count	478 X 10 ⁹ /L (150-400)
CXR	diffuse patchy infiltrates

What is the most appropriate management?

	Ivermectin and PRN salbutamol nebulisers
	IV Hydrocortisone and PRN salbutamol nebulisers
	IV Antibiotics with PO prednisolone and PRN salbutamol
	IV antibiotics until stable then antiretroviral therapy
	Discuss with ITU with a view to transferring care

Dashboard

□ Question 90 of 155

□ □

A 44-year-old businessman was admitted to the general medical take with fever, jaundice and headaches. He had returned from a business trip in Hong Kong one month ago. He is a keen river sailor and has been unable to sail for the last two weeks.

On examination he is tachycardic with temperature of 39.5°C. He appears confused and is combative during the examination. His chest has scattered crackles bibasally with some right upper quadrant abdominal pain

Investigations

Hazy lung infiltrates bibasally

Haemoglobin	135 g/L (130180)
White cell count	17.8 × 10 ⁹ /L (4.011.0)
Neutrophil count	15.7 × 10 ⁹ /L (1.57.0)
Platelet count	413 × 10 ⁹ /L (150400)

Serum C-reactive protein	345 mg/L (<10)
Serum urea	13.3 mmol/L (2.57.0)
Serum total bilirubin	110 mol/L (122)
Serum alanine aminotransferase	117 U/L (535)
Serum alkaline phosphatase	110 U/L (45105)
Serum gamma glutamyl transferase	61 U/L (<50)

What is the most likely diagnosis?

	Dengue Fever
	HIV seroconversion

Chest X- Ray		
		Acute hepatitis A
		Malaria
		Leptospirosis
<p>Leptospirosis is the most likely diagnosis. The river sailing puts this gentleman at risk of contact with contaminated water from animal urine. Incubation is between 4-14 days. Typical symptoms include high fever, headache, muscle aches, vomiting and may have meningitis and jaundice.</p> <p>Hong Kong is not a malaria endemic region nor is it a common region for Dengue Fever. HIV seroconversion would not explain jaundice or deranged liver function. Acute Hepatitis A infection is prevalent in Hong Kong and incubation period is between 2 - 6 weeks but infection would not explain the neurological symptoms.</p> <p>Leptospirosis</p> <p>Also known as Weil's disease*, leptospirosis is commonly seen in questions referring to sewage workers, farmers, vets or people who work in abattoir. It is caused by the spirochaete <i>Leptospira interrogans</i> (serogroup L icterohaemorrhagiae), classically being spread by contact with infected rat urine. Weil's disease should always be considered in high-risk patients with hepatorenal failure</p> <p>Features</p> <ul style="list-style-type: none"> • fever • flu-like symptoms • renal failure (seen in 50% of patients) • jaundice • subconjunctival haemorrhage • headache, may herald the onset of meningitis <p>Management</p> <ul style="list-style-type: none"> • high-dose benzylpenicillin or doxycycline <p>*the term Weil's disease is sometimes reserved for the most severe 10% of cases that are associated with jaundice</p> <p>NIL</p> <p>justquestion</p> <p>0</p> <p>ffffffffffffffff</p> <p>16_B_2</p> <p>1_1144</p>

□ Question 91 of 155

□ □

A 40-year-old yoga teacher is reviewed in respiratory clinic following a recent presentation to the emergency department with fever and lethargy. The patient describes a six month history of night sweats, weight loss and progressive reduced exercise capacity that has left him unable to work. During a short admission to hospital he was diagnosed with active pulmonary tuberculosis on the basis of a suggestive chest x-ray and sputum microscopy. He was initiated on standard combination therapy for tuberculosis and discharged for outpatient follow-up.

At clinic, the patient denies feeling any significant improvement in his symptoms. A detailed social history is taken and the patient reports no risk factors for blood-borne viral infections. However, he does report spending 9 months in rural India three years previously as part of his yoga study.

Examination shows the patient to be noticeably cachexic, with a further 3 kg weight loss recorded compared to at the time of hospital admission.

Please see below for results of investigations requested while the patient was an inpatient. Following review of the results, the need for intravenous treatment is explained to the patient.

HIV serum antibody	not detected
HIV serum RNA	not detected

Phenotypic indirect drug susceptibility testing: rifampicin (resistant); ofloxacin (sensitive); moxifloxacin (sensitive); isoniazid (resistant); amikacin (sensitive); kanamycin (sensitive).

What is the appropriate duration of intravenous treatment for this patient?

	9-12 months
	18-24 months
	1-2 months
	6-8 months

Question 92 of 155

□ □

A 43-year-old gentleman presents with bloody diarrhoea. He is HIV positive and has a CD4 count of 150 cells/ μ L.

He had been on a trip to Zimbabwe 10 months previously. Over the past 2 weeks, he had symptoms of anorexia and mild abdominal discomfort. These had progressed on to severe abdominal cramps and bloody diarrhoea.

He has a temperature of 37.8°C, a blood pressure of 100/60 and a pulse of 111/min. On examination, he looks unwell, is emaciated and has generalised tenderness on examination of his abdomen. There is no guarding or peritonitis.

What is the most likely causative organism?

	<i>Giardia lamblia</i>
	<i>Toxoplasma gondii</i>
	<i>Entamoeba histolytica</i>
	<i>Cytomegalovirus</i>
	<i>Strongyloides stercoralis</i>

□ □

A 35-year-old gentleman presents to the emergency department with worsening shortness of breath on exertion. His symptoms have been progressing for two weeks, and he now finds it difficult to take a full breath. He has no chest pain and has not been coughing but he has been feeling increasingly fatigued. He has a past medical history of HIV. He has been struggling to take his tablets recently. He is unsure of the names of any tablets, but he knows that he is supposed to take one tablet each day at the same time and to take two tablets twice a day on Mondays, Wednesdays, and Fridays. He has no other medical problems.

On examination, auscultation shows normal breath sounds.

Observations:

Saturations	93%
Respiratory rate	22/min
Blood pressure	136/71mmHg
Heart rate	91/min
Temperature	37.6°C

On mobilisation, his saturations reduce to 88%.

Chest X-ray is clear.

What investigation is most likely to be diagnostic?

	CT pulmonary angiogram
	High resolution CT chest
	ECG
	Echocardiogram

□ Question 96 of 155

A 46-year-old Ghanaian woman was flying from Ghana to San Francisco, USA when she was noticed to be confused and behaving inappropriately on the plane. She was talking loudly to herself, complaining of a headache, and also appeared to be hearing voices. She had one episode of incontinence on the plane. During the transit in London, she was brought to the nearest hospital for investigations.

On examination, she was drowsy and slow to respond to questions. Her temperature was 37.3°C, heart rate of 98 bpm, blood pressure of 138/92 mmHg, respiratory rate of 16, and oxygen saturations were 100% on air. Her pupils were 3mm bilaterally, equal and reactive. Her neck was supple and there was mild photophobia. Her abbreviated mental test score was 6/10.

Her investigations revealed:

C Reactive protein	24 mg/l
Haemoglobin	128 g/l
White cell count	$11.6 \times 10^9/L$
HIV antibody serology	positive
HIV viral load	19000 copies/ml
CD4+ T lymphocyte count	35 cells/mm ³
Na+	136 mmol/l
K+	4.9 mmol/l
Urea	7.2 mmol/l
Creatinine	108 µmol/l
Corrected calcium	2.32 mmol/l
Plasma glucose	5.8mmol/l

Chest X-Ray: Lung fields clear

Computer Tomography (CT) head scan: Hypodense lesions involving the medial temporal regions. Lesions enhance with contrast.

Cerebro-spinal fluid (CSF) analysis:

Opening pressure	20 cmH2O
Protein	1.2 g/L
White cell count	50 per mm ³ (predominantly mononuclear cells)
Red cell count	5 per mm ³
Glucose	4.8 mmol/l
Gram stain	No organisms seen

What is the next most appropriate management step?

	Intravenous acyclovir
	Oral prednisolone
	Highly Active Anti-Retroviral Therapy (HAART)
	Intravenous fluconazole
	Pyrimethamine and Sulfadiazine

Dashboard

Question 96 of 155

A 46-year-old Ghanaian woman was flying from Ghana to San Francisco, USA when she was noticed to be confused and behaving inappropriately on the plane. She was talking loudly to herself, complaining of a headache, and also appeared to be hearing voices. She had one episode of incontinence on the plane. During the transit in London, she was brought to the nearest hospital for investigations.

On examination, she was drowsy and slow to respond to questions. Her temperature was 37.3°C, heart rate of 98 bpm, blood pressure of 138/92 mmHg, respiratory rate of 16, and oxygen saturations were 100% on air. Her pupils were 3mm bilaterally, equal and reactive. Her neck was supple and there was mild photophobia. Her abbreviated mental test score was 6/10.

Her investigations revealed:

C Reactive protein	24 mg/l
Haemoglobin	128 g/l
White cell count	$11.6 \times 10^9/L$
HIV antibody serology	positive
HIV viral load	19000 copies/ml
CD4+ T lymphocyte count	35 cells/mm ³
Na+	136 mmol/l
K+	4.9 mmol/l
Urea	7.2 mmol/l
Creatinine	108 µmol/l
Corrected calcium	2.32 mmol/l
Plasma glucose	5.8mmol/l

Chest X-Ray: Lung fields clear

Computer Tomography (CT) head scan: Hypodense lesions involving the medial temporal regions. Lesions enhance with contrast.

Cerebro-spinal fluid (CSF) analysis:

Opening pressure	20 cmH2O
Protein	1.2 g/L
White cell count	50 per mm ³ (predominantly mononuclear cells)
Red cell count	5 per mm ³
Glucose	4.8 mmol/l
Gram stain	No organisms seen

What is the next most appropriate management step?

	Intravenous acyclovir
	Oral prednisolone
	Highly Active Anti-Retroviral Therapy (HAART)
	Intravenous fluconazole
	Pyrimethamine and Sulfadiazine

□ Question 97 of 155

□ □

A 23-year-old student presented to his GP with fever and epistaxis. The fever had started 6 days earlier. It had been associated with a headache and malaise. Following clinical examination his doctor prescribed him amoxicillin which he took for 3 days but without any improvement. He later became so ill that he refused to eat and started to vomit.

His history included mumps at the age of nine. His father had been diagnosed with liver cirrhosis 2 years ago due to excessive alcohol consumption. He is a regular smoker for the last 10 years and lives in the dorm. Two weeks earlier he had been in rural Central Africa as a reporter covering the conflict there. He denied being vaccinated for any disease before going there but did take anti-malarial tablets.

On examination he appeared ill. His temperature was 38°C. He was jaundiced. Eye examination revealed conjunctival hemorrhages on both eyes. All other systems were normal.

The following investigations had been requested:

Hb	13 g/dl
platelets	$170 \times 10^9/l$
WBC	$4 \times 10^9/l$
MCV	85 fl
MCH	0.4 fmol/cell
MCHC	20 mmol/l
Na+	135 mmol/l
K+	4 mmol/l
Creatinine	80 $\mu\text{mol/l}$
Urea	3 mmol/l
ESR	60 mm/hr
Alkaline phosphatase	100 IU/l

Alanine transaminase	400 IU/l
Aspartate transaminase	200 IU/l
Bilirubin	25 µmol/l (direct 18 umol/l)
Serum albumin	40 g/l
Prothrombin time	prolonged
Partial thromboplastin time	prolonged
Urine analysis	Albumin + ,acetone ++ ,bile pigment ++ ,urinary urobilinogen +
Thick Blood film for malaria	negative

What is the most likely diagnosis?

<input type="radio"/>	Yellow fever
<input type="radio"/>	Primary sclerosing cholangitis
<input type="radio"/>	Leptospirosis
<input type="radio"/>	Falciparum malaria
<input type="radio"/>	Dengue fever

Question 98 of 155

A 27-year-old man who recently immigrated to the UK from Ethiopia complains of a chronic cough with night sweats for five weeks. On direct questioning, he also admits coughing up small volumes of bright red blood a few times. This has made him especially concerned as he his father died from lung related problems following chronic coughs.

Following a chest X-ray and blood tests he is diagnosed with TB and contact tracing is started. His 25-year-old male partner lives with him and is identified as being at high risk of contracting TB. The partner undergoes Mantoux testing and has a 2mm area of induration. He has never had BCG vaccination as far as he is aware and has no vaccination scar. What is the most appropriate management that should be offered to the partner?

	BCG vaccination
	HIV testing and if negative then BCG vaccination
	Prophylactic anti-TB treatment
	Repeat TB screening in six weeks
	No further management needed

Question 99 of 155

A 38 year-old woman presented to the medical outpatient clinic with an 8 month history of deteriorating vision. She also complained of a pruritic rash intermittently affecting her forearms and neck. She had recently migrated to the UK from Guinea, where she had lived since birth. She had suffered from malaria as a child but had been fit and well since. She did not smoke and drank 6-10 units of alcohol per week.

On examination, her temperature was 36.7°C, pulse was 68 beats per minute and blood pressure was 124/80 mmHg. Her chest was clear on auscultation and heart sounds were normal. Fundoscopy was not possible due to clouding of both corneas. There was evidence of a mottled rash over the forearms and neck with a leopard print appearance.

Investigations:

Haemoglobin	141 g/L (130-180)
White cell count	6.7 x ⁹ /L (4.0-11.0)
Neutrophil count	3.0 x ⁹ /L (2.0-7.5)
Lymphocyte count	1.7 x ⁹ /L (1.3-3.5)
Eosinophil count	0.6 X ⁹ /L (0.1-0.4)
Platelets	260 x ⁹ /L (150-400)

Sodium	138 mmol/L (135-145)
Potassium	4.3 mmol/L (3.5-5.0)
Urea	7.2 mmol/L (2.5-7.5)
Creatinine	61 mol/L (25-95)
Fasting plasma glucose	5.0 mmol/L (3.0-6.0)

Giemsa-stained blood film	No abnormality detected
---------------------------	-------------------------

Given the likely diagnosis, what is the most appropriate treatment?

	Diethylcarbamazine (DEC)
	Ivermectin
	Benzinidazole
	Albendazole
	Praziquantel

Question 100 of 155

□ □

A 47-year-old man is referred by the emergency department with increasing shortness of breath. He is a known HIV patient managed by the local GUM consultants. He is not on any antiretroviral treatment. He presents with a two-week history of worsening shortness of breath. He is now breathless on minimal exercise. He has a non-productive cough and has felt lethargic for the last week. On examination he is afebrile, his blood pressure is 120/89 mmHg and he is slightly tachycardic at 110bpm. His respiratory rate is 18 at rest with saturations on 98% on air. When he mobilises to the toilet he becoming very tachypnoeic and his saturations drop to 90%. His blood tests are as follows:

Hb	110 g/l
Platelets	201 * 10 ⁹ /l
WBC	9.6 * 10 ⁹ /l
Neutrophils	4.5 * 10 ⁹ /l

Na ⁺	138 mmol/l
K ⁺	4.1 mmol/l
Urea	7.8 mmol/l
Creatinine	20 µmol/l
CRP	70 mg/l

Bilirubin	5 µmol/l
ALP	89 u/l
ALT	43 u/l
Albumin	34 g/l

An ABG is done which shows

pH	7.35
pO2	7.7
pCO2	4.6
HCO3-	21
BE	-3
Lactate	2.2

His chest x-ray shows fine bilateral reticular nodular shadowing.

What is the most appropriate treatment to start in this gentleman?

	Tazocin
	Co-trimoxazole
	Aciclovir
	Co-trimoxazole and corticosteroids
	Highly active anti-retroviral treatment

□ Question 102 of 155

An 80-year-old lady presents from a nursing home with a one-day history of fevers, drowsiness and vomiting. She has been unwell, not eating for the past 3 days according to her carer. Recently she has been exhibiting behavioural changes, crying and agitation when lights are turned on in the room, and holding her neck. She has a back ground of Alzheimer's dementia, hypertension, congestive cardiac failure(CCF) and chronic kidney disease.

On examination, she is febrile with a temperature of 38.1oC. Heart rate 112bpm, respiratory rate 20breaths per minute and oxygen saturations of 94% on air. On auscultation, there are bibasal crepitations and cardiovascular examination is consistent with mild CCF. There is neck stiffness and photophobia on cranial nerve examination, pupils equal and reactive to light. Kernig's sign is positive.

Investigations:

Na+	129mmol/l
K+	4.8 mmol/l
Urea	10.9 mmol/l
Creatinine	123 µmol/l
Serum glucose	5.9mmol/l
C Reactive protein	95mg/l
Haemoglobin	126 g/l
White cell count	16.4 x 10 ⁹ /L
INR	1.2

Cerebro-spinal fluid (CSF) analysis:

Opening pressure	25 cmH2O
Protein	1.8 g/L
Glucose	2.6 mmol/l

White cell count	>1000 per mm ³
Gram Stain	Gram-positive rods seen
Colour	Cloudy, turbid

What is the likely causative organism?

	<i>Streptococcus pneumoniae</i>
	<i>Listeria monocytogenes</i>
	<i>Staphylococcus aureus</i>
	<i>Neisseria meningitidis</i>
	<i>Haemophilus influenzae</i>

Question 103 of 155

□ □

A 72-year-old male diabetic is admitted to the hospital via the Emergency Department with severe cellulitis of his right arm. He is hypertensive and also suffers from coronary artery disease.

On examination he is febrile, with a temperature of 38.5°C. His pulse is 112 bpm and his blood pressure is 150/95 mmHg.

His right arm is grossly swollen and tender, with marked erythema and discharge of small amounts of pus.

Lab reports reveal:

Hb	90 g/l
MCV	71 fl
WBC	23 * 10 ⁹ /l
Plt	500 * 10 ⁹ /l
Urea	9.2 mmol/l
Creatinine	145 µmol/l

Urine examination reveals proteinuria 1+ and glycosuria 2+

Preliminary blood cultures post admission reveal the growth of MRSA.

Which of the following would be the most appropriate antibiotic for this patient?

	IV Vancomycin
	IV Flucloxacillin
	IV Linezolid
	IV Rifampicin

	IV Gentamicin

Question 104 of 155

A 45 year old man presents to the Emergency Department. He told the admitting doctor that he had fallen onto his left hip last night whilst he had been drinking at home. He had extensive bruising around his hip and some bony tenderness and so a hip x-ray was taken.

His x-ray shows no fracture nor bony abnormality, but several 2x4mm specs of calcification are visible in his psoas and thigh muscles.

Later on his wife asks to speak to you in confidence. She states that over the last year her husbands personality has gradually changed and he is sometimes forgetful. He lost his job 3 months ago as an engineer. He had worked for 8 years in Peru on an engineering project in his thirties. He drinks 8 units of alcohol per day and seems to have had a low mood for several years.

Yesterday he had fallen, lost consciousness, and had a jerking of his arms and legs lasting 1 minute. He had hit his hip on a coffee table and had wet himself. Afterwards he felt tired and lethargic but had refused to go to hospital.

What is the most likely diagnosis?

	HIV dementia
	Alcohol withdrawal seizure
	Neurocysticercosis
	Emboli secondary to calcified aortic valve
	Primary idiopathic epilepsy

His x-ray shows no fracture nor bony abnormality, but several 2x4mm specs of calcification are visible in his psoas and thigh muscles.

Later on his wife asks to speak to you in confidence. She states that over the last year her husbands personality has gradually changed and he is sometimes forgetful. He lost his job 3 months ago as an engineer. He had worked for 8 years in Peru on an engineering project in his thirties. He drinks 8 units of alcohol per day and seems to have had a low mood for several years.

Yesterday he had fallen, lost consciousness, and had a jerking of his arms and legs lasting 1 minute. He had hit his hip on a coffee table and had wet himself. Afterwards he felt tired and lethargic but had refused to go to hospital.

What is the most likely diagnosis?

	HIV dementia
	Alcohol withdrawal seizure
	Neurocysticercosis
	Emboli secondary to calcified aortic valve
	Primary idiopathic epilepsy

Question 108 of 155

□ □

A 48-year-old farmer presents with a four-day history of headache, pyrexia and vomiting. He has recently been undergoing chemotherapy for mantle cell lymphoma and successfully completed his fourth cycle three days ago. During his treatment, he has tried to maintain an active lifestyle and has continued to work on his dairy farm. He has no other past medical history, he does not smoke or drink. On examination, the patient is drowsy and pyrexia at 38.6 degrees. You note no rashes on his skin. He displays neck stiffness and photophobia. You are unable to formally perform a neurological examination but you note no obvious facial asymmetry and the patient is moving all four limbs. Both plantars are downgoing.

Blood tests are as follows:

Hb	98 g/l
Platelets	$78 \times 10^9/l$
WBC	$0.9 \times 10^9/l$
Neutrophils	$0.3 \times 10^9/l$

Na ⁺	146 mmol/l
K ⁺	4.3 mmol/l
Urea	8 mmol/l
Creatinine	99 μ mol/l
CRP	170 mg/l

A lumbar puncture is performed and the cerebrospinal fluid examination is as follows:

WCC	$200 \times 10^6/litre$ (70% neutrophil 25% lymphocytes)
RBC	$4 \times 10^6/litre$
Glucose	1.7 mmol/l (normal 3.3-4.4 mmol/l)

Microscopy	No organisms on gram stain
Appearance	cloudy

The patient is immediately commenced on intravenous ceftriaxone for suspected bacterial meningitis. At 48 hours after initial admission, blood and cerebrospinal fluid cultures are still awaited. The patient has demonstrated no change in clinical state. What is an appropriate additional therapy?

	Hourly neurological monitoring
	Intravenous acyclovir
	Intravenous ampicillin
	Intravenous rifampicin
	Intravenous amphotericin B

Question 109 of 155

□ □

A 32 year old man presents with left lower limb weakness for the past three weeks. Over the past week his condition has got much worse. He has lost his appetite and about six kilograms in the last two months. In the same period he reported recurrent bleeding from the nose.

With the help of three months of nicotine transdermal patches and vareniciline he is now no longer actively smoking. He is married and works as a salesman in a pharmaceutical company. For the last year he has been to many destinations around the world as part of his job.

On examination he appeared ill. He was oriented in time, place, and person, but was mentally slow in understanding commands during examination. The power in the left leg was grade 2 for all muscle groups. Tone, sensation, coordination and reflexes were all normal. The right leg was normal. No abnormality detected in other systems. The following investigation were ordered:

Hb	10g/dl
Platelets	$10 \times 10^9/l$
WBC	$4 \times 10^9/l$
Neutrophils	60%
Lymphocytes	34%
Na ⁺	135 mmol/l
K ⁺	4 mmol/l
Creatinine	95 μ mol/l
Urea	4 mmol/l

Urine analysis: Clear

MRI brain showed bilateral multiple hyperintense demyelinating lesions involving sub cortical areas without any mass effect.

What is the most appropriate thing to do?

	CSF analysis for oligoclonal bands
	Brain biopsy
	CSF analysis for herpes simplex virus (HSV)
	HIV test
	Stop vareniciline

Question 111 of 155

□ □

A 52-year-old male presents with a cough, fatigue, fever, and shortness of breath. He had been feeling unwell for around 6 months with recurrent colds that he couldn't seem to shake off. Over this period he had lost around one and a half stone in weight. He attributed this to a poor appetite. His only past medical history was asthma. He had been a widower for 7 years and was a keen wildlife photographer which had allowed him to travel the world. His last trip had been to Africa 2 years ago.

On examination he had a temperature of 38.2°C, heart rate is 102/min and regular, blood pressure 110/70 mmHg and saturations 92% air. He had fine bibasal crackles on chest auscultation. Heart sounds were normal. Arterial blood gas showed a type 1 respiratory failure. Chest x-ray showed bilateral pulmonary infiltrates. He was treated with intravenous antibiotics. After two days of admission, his condition worsened and his type 1 respiratory failure worsened and he was given continuous positive airway pressure (CPAP). The beta glucan test came back negative. Urinary antigens were negative. The patient remarked that he had noted that his vision in his right eye was blurred and he had noted flashing lights and spots in the same eye.

What is the most likely diagnosis?

	Pneumocystis pneumonia
	CMV pneumonia
	Fungal pneumonia
	Legionella pneumonia
	Asthma exacerbation

□ □

A 36-year-old Somali male presents on the medical take with a severe generalised headache associated with nausea and vomiting. He has been living in the UK for the last 10 years. He was diagnosed with HIV 5 years ago and has been well maintained on therapy with an undetectable viral load and a CD4 count of 500 cells/mm³.

He has a long history of headaches since the age of 10 which are normally controlled with simple analgesia. Over the last 2 days he has been suffering with a particularly bad attack which culminated in him becoming aggressive and vomiting profusely. He was noted to have a tonic-clonic seizure whilst in accident and emergency which resolved with diazepam.

Clinical examination reveals a pulse of 78 beats per minute, a blood pressure of 130/90, oxygen saturations of 98% on air and a temperature of 36.8 degrees. There was no focal neurological defects.

A CT scan subsequently showed cystic and calcified lesions within the brain and mild hydrocephalus.

What is the most likely diagnosis?

	Tuberculous meningitis
	Cryptococcal meningitis
	Lymphoma
	Neurocysticercosis
	Human african trypanosomiasis

□ Question 113 of 155

□ □

A 19 year-old University student presented to her General Practitioner with a three month history of intermittent diarrhoea and anorexia. She had lost approximately 10 kg of weight over a similar period. The patient had no previous abdominal symptoms and no significant past medical history. The symptoms had started several weeks after her return from a gap year expedition to Mali. On close questioning the patient did recall a short-lived intensely itchy erythematous rash on one of her feet while she was in Africa. This had spontaneously resolved and not subsequently recurred.

Initial investigations are listed below:

Hb	12.8 g/dl
Platelets	$198 \times 10^9/l$
WBC	$10.8 \times 10^9/l$
Neutrophils	$5.2 \times 10^9/l$
Lymphocytes	$2.1 \times 10^9/l$
Monocytes	$0.8 \times 10^9/l$
Eosinophils	$2.7 \times 10^9/l$
Basophils	$0.0 \times 10^9/l$

Na ⁺	136 mmol/l
K ⁺	4.2 mmol/l
Urea	3.9 mmol/l
Creatinine	78 μ mol/l

Stool microscopy: *Strongyloides stercoralis* larvae
Strongyloides stercoralis filariform larvae IgG: positive

Under supervision from Infectious Disease department the patient was treated with Ivermectin.

What is the best method to assess for *Strongyloides stercoralis* eradication six months after completion of treatment course?

	Repeat blood eosinophil count
	Assessment of patient symptoms
	Repeat <i>Strongyloides stercoralis</i> serology
	Repeat stool microscopy on two occasions one week apart
	Repeat stool microscopy with stool concentration technique

Creatinine	78 µmol/l

Stool microscopy: *Strongyloides stercoralis* larvae
Strongyloides stercoralis filariform larvae IgG: positive

Under supervision from Infectious Disease department the patient was treated with Ivermectin.

What is the best method to assess for *Strongyloides stercoralis* eradication six months after completion of treatment course?

	Repeat blood eosinophil count
	Assessment of patient symptoms
	Repeat <i>Strongyloides stercoralis</i> serology
	Repeat stool microscopy on two occasions one week apart
	Repeat stool microscopy with stool concentration technique

□ Question 114 of 155

A 32-year-old woman attends the infectious diseases clinic for an urgent review. The patient had presented to the emergency department the previous weekend complaining of various constitutional symptoms. A set of blood cultures had been taken as the patient was febrile at presentation. Assessment in the emergency department had not identified a clear cause for the patient's illness and she had been discharged home with advice to attend her GP surgery if her symptoms did not resolve in the coming days. The patient had been recalled to hospital for review after the blood cultures taken during her presentation yielded a positive result. Selected investigation results from the patient's emergency department attendance are given below.

At her review appointment, the patient recounted her recent symptoms. She described a 3-week history of intermittent fever, malaise and reduced appetite. On direct questioning, she did recall experiencing excessive overnight sweating on a few occasions but had not experienced joint pains. The patient denied other symptoms, including those associated with the respiratory, urinary tract and neurological systems.

The patient was otherwise healthy, with no significant past medical history. She took no regular medications and had no known medication allergies. The patient was a chartered accountant and lived with her husband and 5-year-old daughter. The patient had returned from a holiday in Turkey 4 weeks previously. During her holiday she had visited relatives in a rural village and recalled consuming local dairy products that she suspected had not been pasteurised.

On general examination, the patient appeared to be tired and pale. Examination of the patient's abdomen revealed palpable hepatomegaly and splenomegaly. Examinations of the respiratory, cardiovascular, neurological and musculoskeletal systems were unremarkable. Selected investigation results from the patient's emergency department attendance are given below.

Haemoglobin	117 g / dL
White cell count	3.9×10^9 / microlitre
Neutrophils	2.1×10^9 / microlitre (reference 1.8-7.8)
eGFR	> 90 ml / min / 1.73 m ²
Alkaline phosphatase	134 U / L (reference 35-100)
ALT	57 U / L (reference 3-36)
Bilirubin	24 micromol / L (reference < 26)

C-reactive protein	68 mg / L (reference < 7)
Urine dipstick	No abnormality detected
Blood cultures	Small gram-positive coccobacilli; consistent with <i>Brucella</i> species
Chest x-ray	Clear lung fields; no evidence of consolidation or effusion

The likely diagnosis of Brucellosis was discussed with the patient. She expressed a very strong preference to receive treatment on an outpatient basis so that she would not be separated from her family.

What is the appropriate treatment regime?

<input type="radio"/>	Doxycycline monotherapy for 2 weeks
<input type="radio"/>	Proguanil with atovaquone for 3 days
<input type="radio"/>	Clarithromycin and amoxicillin for 1 week
<input type="radio"/>	Isoniazid, rifampicin, pyrazinamide and ethambutol for 8 weeks
<input type="radio"/>	Doxycycline and rifampicin for 6 weeks

□ Question 115 of 155

□ □

A 40-year-old woman is referred to the infectious diseases team after attending her GP practice requesting advice regarding antibiotic prophylaxis for Lyme disease. The patient explains that she is planning on a 2 week long walking holiday in the Lake District National Park in Cumbria, United Kingdom and that she is concerned about the risk associated with receiving tick bites during this period. Lyme disease is a particular concern for the patient as her younger sister had suffered serious neurological complications from the condition secondary to a tick bite in the Scottish Highlands. Concern about contracting Lyme disease herself had prevented her from partaking in her hobby of cross country walking for the past 2 years but she had now decided to confront her fear by undertaking the planned trip. After undertaking research on the Internet, the patient was keen to receive prophylactic antibiotics against *Borrelia* species during her trip.

The patient's past medical history included a diagnosis of breast cancer seven years previously. Following this diagnosis, the patient had undergone a wide local excision of the tumour with postoperative chemotherapy. The patient had been given the all clear from her oncologists after five years and had been subsequently been discharged from follow-up. In addition, the patient had experienced long-standing and, at times, troubling symptoms of irritable bowel syndrome.

The patient took regular hyoscine butylbromide as treatment of her gastrointestinal symptoms. The patient stated that she was allergic to penicillin-based antibiotics. Close questioning on this topic revealed that her adverse reaction to a previous course of penicillin V had been a protracted episode of diarrhoea.

The patient lives with her husband and three teenage children. She was employed full-time as a music teacher. The patient did not smoke cigarettes and consumed approximately 10 units of alcohol per week.

What is appropriate management following the patient's request for antibiotic prophylaxis against Lyme disease during her walking holiday?

	Prescribe amoxicillin for the duration of the patient's holiday
	Prescribe amoxicillin for immediate use if she receives a tick bite
	Prescribe doxycycline for the duration of the patient's holiday continued for an additional 10 days after her return home

	Advice on the prevention and management of tick bites only
	Prescribe doxycycline for immediate use if she receives a tick bite

Question 116 of 155

A 60 year old male who is a malnourished alcoholic presents with a chronic cough for the past 6 weeks associated with a low grade fever. The cough is productive of purulent sputum.

Six months previously he had been diagnosed with early stage non-Hodgkin's lymphoma, which had responded well to chemotherapy (doxorubicin, bleomycin, vinblastine, and prednisolone).

On examination his temperature is 37.8°C, blood pressure 140/80 mmHg, and his pulse is 96/minute and regular. Auscultation of the chest reveals absence of breath sounds over the left middle lung field. Chest x-ray confirms left upper lobar consolidation.

The following investigations were ordered:

Hb	12 g/dl
Platelets	$180 \times 10^9/l$
WBC	$7 \times 10^9/l$
MCV	85 fl
Na+	140 mmol/l
K+	5 mmol/l
Creatinine	90 μ mol/l
Urea	5 mmol/l
CRP	50 mg/l

Sputum stains partially acid fast bacilli with branching rods

What is the most suitable initial management of this patient?

	Metronidazole + ampicillin
--	----------------------------

	Clarithromycin
	Ceftriaxone + clarithromycin
	Trimethoprim/sulfamethoxazole + amikacin + ceftriaxone
	Isoniazid + rifampin + pyrazinamide + ethambutol

Question 117 of 155

□ □

A 25-year-old HIV-positive male goes to his GP with complaints of headache and left-sided weakness of recent onset. His temperature is 38°C, blood pressure is 115/70 mmHg, respirations are 14/min and pulse is 73/min.

Neurological examination reveals decreased power, hyperreflexia in the left upper and lower limb with associated upgoing plantars. CT head shows multiple ring-enhancing lesions.

What is the most appropriate next step in management?

	Trimethoprim-sulfamethoxazole
	Sulfadiazine and pyrimethamine
	Brain irradiation
	Brain biopsy
	Start albendazole

Question 118 of 155

□ □

A 41-year-old man with poorly controlled type 1 diabetes mellitus presents with a nodular lesion on the right-side of his face around the angle of the jaw. One month ago he had a tooth extraction at the dentist. The nodule is around 2 cm in diameter, raised and purple-red in colour. On examination a sinus tract is seen in the middle of the nodule which is draining a blood-stained fluid.

Microscopy of the discharge shows microscopic yellow granules.

What is the most likely causative organism?

	<i>Actinomyces israelii</i>
	<i>Tunga penetrans</i>
	<i>Klebsiella</i>
	<i>Pseudomonas aeruginosa</i>
	<i>Escherichia coli</i>

□ Question 119 of 155

□ □

A 27-year-old nurse attends the emergency department and reports she has just suffered a significant needle-stick injury while caring for her patient on the intensive care unit. While providing her patient personal care with her colleague, she was injured in the hand by a wide bore stylet needle previously used to introduce an IV cannula to her patient that had not been placed in an appropriate sharps bin. The needle had been visibly blood stained. The nurse had been wearing gloves and had followed correct first aid procedure for needle-stick injuries.

The nurse was very concerned as the patient who had been the needle-stick donor was receiving treatment for the acute neurological phase of rabies. Review of the patients clinical notes (with the consent of the patients next of kin) indicated that he had contracted rabies following a dog bite two months previously in Pakistan. The diagnosis of rabies encephalitis had been made following clinical review by infectious disease experts and the detection of neutralising serum antibodies.

The nurse was previously fit and healthy with no significant past medical history. She did not use any regular medications and had no allergies. She was uncertain if she had had any previous vaccination against rabies, although did recall having a course of injections 10 years previously before she visited family in rural India.

What is the correct management of the needle-stick injury to prevent transmission of rabies?

	Rabies immunoglobulin and full course rabies vaccination
	Booster course rabies vaccination
	Rabies immunoglobulin
	Full course rabies vaccination
	No action required

Dashboard

□ □

A 26-year-old woman presents to the emergency department with right upper quadrant pain which is worse when she takes a deep breath in. Her symptoms started three days earlier and have been progressively getting worse. She has no past medical history and takes no medications apart from the oral contraceptive pill and paracetamol to help control the pain. She has also noticed an increase in vaginal discharge over the last two weeks and has noticed an unpleasant smell with it. She works in an investment bank. On examination, she has right upper quadrant tenderness, but the abdomen is soft and no organomegaly is noticed. Abdominal ultrasound demonstrates the presence of gallstones in the gallbladder but is otherwise normal. What treatment is most likely to resolve the cause of her underlying problem?

	Cholecystectomy
	Trimethoprim
	Antiviral treatment
	Antiretroviral treatment
	Ceftriaxone

Question 121 of 155

A 35 year old man presents to the genitourinary medicine clinic with a 1 week history of ulcer on his penis. It is painless and he feels it might be increasing in size, though there are no other ulcers. He has never had any ulcers before.

He is HIV positive and remains sexually active with one regular male partner. They do not usually use condoms as he strictly adheres to his antiretroviral medication schedule and has an undetectable viral load. However, he has not had intercourse since developing the ulcer as it is too painful.

He had gonorrhoea aged 18 which was treated with antibiotics at the time and he has no history of any other sexually transmitted infections.

He has no other past medical history and no drug allergies. He takes no medications other than his antiretrovirals.

On examination he has a single shallow ulcer 1 x 2 cm on the dorsal surface of the penis with a small rim of surrounding erythema. He has no other rashes or lymphadenopathy. Systemic examination is otherwise unremarkable with no focal neurology.

Swabs from the ulcer are negative for herpes simplex virus 1 and 2.

Penile swabs are negative for chlamydia and gonorrhoea.

Syphilis serology result:

Enzyme immunoassay (EIA) +

Treponema Pallidum particle agglutination assay (TPPA) +

Rapid plasma reagin (RPR) -

What is the best immediate management option?

<input type="checkbox"/>	Intramuscular penicillin G and check repeat syphilis serology

A 54-year-old gentleman attends the Emergency Department, following a dog bite on his forearm 6 hours earlier. This occurred in the United Kingdom. The wound is clean with no active bleeding. There is no damage to underlying structures. He has no past medical history of note and does not take any regular medications. He has no known drugs allergies. He is unsure of his previous immunisation status. What is the most appropriate advice?

	Nothing additional required
	Rabies immunoglobulin
	Rabies vaccination
	Tetanus immunoglobulin
	Tetanus booster vaccination

Question 123 of 155

□ □

A 15-year-old male is investigated following a one week history of fever, non-productive cough, sore throat and headaches. Today he noticed a skin rash. His temperature is 38.5°C, pulse is 90/min, blood pressure is 115/78 mmHg and respirations are 16/min.

On examination his throat is hyperaemic, but there is no cervical lymphadenopathy. Chest auscultation and percussion reveal no abnormalities. You note dusky red, target shaped skin lesions over all four extremities. Chest x-ray reveals interstitial infiltrates in the left lower lobe. Sputum Gram stain reveals polymorphonuclear cells but no organisms.

Which of the following organisms is most likely responsible for this presentation?

	<i>Streptococcus pneumoniae</i>
	<i>Haemophilus influenzae</i>
	<i>Legionella pneumophila</i>
	<i>Mycoplasma pneumoniae</i>
	Epstein Barr virus

Question 124 of 155

□ □

A 27 year-old Lithuanian male presents to the Emergency Department with a short history productive cough, fever and breathlessness. The chest X-Ray shows left upper zone consolidation. His white cell count and CRP are elevated and IV antibiotics are commenced for a community acquired pneumonia. He makes some improvement after 48 hours but remains on 4L of oxygen to maintain adequate saturations. An interferon gamma release assay for mycobacterium is positive.

What would be the correct course of action?

	Send three morning sputum samples for acid fast bacilli
	Arrange a bronchoscopy and washings for acid fast bacilli
	No action, continue antibiotics, repeat CXR in 6 weeks time
	Treat for latent pulmonary tuberculosis with two agents
	Treat for active pulmonary tuberculosis with quadruple therapy

Dashboard

□ Question 126 of 155

□ □

A 23 year-old student presents with a febrile illness, seven days after return from holiday in Thailand. He delayed seeking medical attention because he thought it was 'just a virus', and he had experienced similar self-limiting symptoms when travelling to Vietnam several years earlier. He did not take malaria prophylaxis due to a previous adverse reaction to mefloquine. The illness began two days after his return, when he recorded his temperature at 38.4°C. He also complains of severe generalised joint pains and headache which he describes as 'behind the eyes'. Today he has developed nosebleeds and when he brushed his teeth this morning he noticed that his gums bled.

On examination his temperature is 38.2°C and there is a widespread macular rash with islands of sparing. There are some petechial haemorrhages on the limbs. Cardio-respiratory examination is unremarkable except for tachycardia of 114. Blood pressure is 123/79 mmHg. On palpation of the abdomen you discover tender hepatomegaly. Neurological examination is unremarkable.

On application of a tourniquet to take a blood sample you notice that the area under the tourniquet has become bruised.

Results of blood tests are as follows:

Hb	14.1 g/dl
MCV	94.2 fl
Haematocrit	0.57
Platelets	23 x10 ⁹ /l
WCC	6.1 x10 ⁹ /l

Na ⁺	134 mmol/l
K ⁺	4.6 mmol/l
Urea	3.8 mmol/l
Creatinine	80 µmol/l

--	--

ALT	64 IU/l
ALP	78 IU/l
Bilirubin	13 mol/l
Albumin	28 g/l

Rapid Malaria test	Negative
Thick and thin blood films	Pending

What is the most likely diagnosis?

<input type="radio"/>	Non-falciparum malaria
<input type="radio"/>	Dengue haemorrhagic fever
<input type="radio"/>	Lassa fever
<input type="radio"/>	Meningococcal septicaemia
<input type="radio"/>	HIV seroconversion

□ Question 128 of 155

A 75-year-old retired plumber presents to the emergency department with recurrent urinary tract infections. He has been treated by his GP four times in the last six months with this complaint, with trimethoprim twice and a further two courses of amoxicillin. He is confused on this presentation and is will not comply with a full neurological examination. His past medical history includes a stroke and a known gastric ulcer. An ultrasound of his renal tract did not reveal any structural defects of hydronephrosis. His son reveals that he is under investigation for a possible haematological malignancy, and had a bone marrow biopsy two days ago. On examination, his heart rate is 115/min, respiratory rate 18/min, blood pressure 134/89mmHg. His respiratory, cardiovascular and abdominal examinations are all unremarkable, other than a soft ejection systolic murmur. He has a tender prostate. His blood reveal:

Hb	12.7 g/dl
Platelets	80 * 10 ⁹ /l
WBC	17.1 * 10 ⁹ /l

Na ⁺	141 mmol/l
K ⁺	3.5 mmol/l
Creatinine	77 µmol/l
CRP	99 mg/l
PSA	6 ng/dl

Given the likely diagnosis, what is the recommended treatment course?

	No treatment required
	One week course of co-amoxiclav
	Tamsulosin

	Finasteride
	Four week course of ciprofloxacin

Dashboard

Question 129 of 155

A 31 year-old male originally from Russia who is known to be HIV positive presents with a rash. On examination there are purple-red cutaneous macules and papules on the back, neck and oral mucosal membrane.

Blood results reveal:

Hb	141 g/l
Platelets	327 * 10 ⁹ /l
WBC	4.2 * 10 ⁹ /l
Na ⁺	141 mmol/l
K ⁺	3.7 mmol/l
Urea	4.6 mmol/l
Creatinine	59 µmol/l
Bilirubin	27 µmol/l
ALP	97 u/l
ALT	44 u/l
Albumin	30 g/l
HIV viral load	14,000 copies / ml
CD4 cell count	124 cell/mm ³

A skin biopsy is performed and the report is below:

Spindle cells present. Mitotic activity is moderate. Abnormally dense and irregular blood vessels. Intracellular hyaline bodies present.

Which virus is likely to be responsible for these lesions?

	CMV
	EBV
	HIV-2
	HHV-8
	HPV-8

□ Question 130 of 155

A 66 year old lady, originally from Pakistan, has lived in the UK for 10 years. She has type 2 diabetes mellitus which is controlled with metformin only.

For the last few years she has had multiple lumps over her whole body but this hasn't bothered her as it has been there for several years and not got too much worse. She has been seeing the diabetic foot care team due to several traumatic shoe healing ulcers on her feet.

Over the past few weeks she has been feeling increasingly unwell. She has had a fever, pain in her knees and elbows, sore painful eyes. She also complains of painful swelling in her ring and little fingers on her right hand.

On examination her temperature is 37.8°C. Her pulse is 91 beats/minute and her RR is 18 breaths/minute. Her oxygen saturations are 97% on room air.

She has a multiple nodular lesions over her whole body in a symmetrical distribution. Sizes of these nodules range from 2cm - 4cm. These lesions are not painful, in fact with the larger ones she is unable to feel you touching them. On her shins there are several hot painful nodules which are uncomfortable to touch. She has a saddle deformity of her nose. There are several scars on her hands, and an ulcer on the lateral dorsum of her foot. Cardiorespiratory and abdominal examination is essentially normal. Both knees and elbow are slightly erythematous and swollen. She has weakness abducting her little and index finger on her left hand and has no sensation in her left little finger. There is a non-painful 1x4 cm lump two centimetres distal to her left medial epicondyle.

Urinalysis reveals ++ of protein and + of blood.

Blood sugar: 8.8 mmol/L

On the clinical information alone what investigation is most likely to secure the diagnosis?

	Serum cANCA antibody
	Serum dsDNA antibody
	Renal biopsy

	Skin biopsy
	Serum ANA antibody

□ Question 133 of 155

A 38 year-old intravenous drug user presented to accident and emergency with a 10-day history of severe watery diarrhoea and abdominal cramps. Her past medical history included treatment for a groin abscess 3 years previously. She could not remember ingesting any possible causative food and had not travelled abroad. She smoked 15 cigarettes per day and drank 30-40 units of alcohol per week.

On examination, her temperature was 36.8°C, heart rate 100 beats per minute, blood pressure 92/58 mmHg, respiratory rate 18 breaths per minute and oxygen saturations 100% on room air. Her tongue appeared dry with white patches evident on the hard palate and throat. The JVP was not visible. Her chest was clear on auscultation and heart sounds were normal. The abdomen was soft on palpation with some mild central abdominal tenderness.

Investigations:

Haemoglobin	170 g/L
White cell count	$4.5 \times 10^9/l$
Neutrophil count	$3.0 \times 10^9/l$
Lymphocyte count	$0.1 \times 10^9/l$
Eosinophil count	$0.4 \times 10^9/l$
Platelets	$423 \times 10^9/l$

Sodium	132 mmol/l
Potassium	3.0 mmol/L
Urea	13.0 mmol/L
Creatinine	110 mol/L
Alkaline phosphatase	57 IU/L
Alanine aminotransferase	60 IU/L
Gamma-glutyl transferase	67 IU/L

Bilirubin	19 mol/L
Albumin	29 g/L

Abdominal x-ray: No abnormality detected
Stool culture: No growth at 48 hours

What additional staining technique should be used for analysing the stool sample?

	Ziehl-Neelson
	Romanowsky
	Periodic acid-Schiff
	Sudan
	Silver

Dashboard

Question 135 of 155

□ □

A 44-year-old white male presents to his GP with a long history of joint pains in several joints, which has gradually affected his ability to work on his farm. He has seen another doctor before but no diagnosis was made. He has been taking ibuprofen with partial relief. He has now developed fever, diarrhoea and weight loss. He denies any genitourinary or eye symptoms. He does not use tobacco, alcohol or drugs.

On examination he has generalised lymphadenopathy and non-deforming arthritis. Small intestinal biopsy reveals macrophage infiltration into the lamina propria.

Which of the following is the most likely diagnosis?

	Reactive arthritis
	Sarcoidosis
	Inflammatory bowel disease
	Whipple's disease
	Coeliac disease

□ □

The Medical Emergency Team was called to the interventional radiology department to review a 48 year-old farmer who was attending for liver biopsy. The procedure itself was uneventful but a few minutes afterwards he became acutely unwell and short of breath. His past medical history was unremarkable apart from on-going investigation for deranged liver function tests. He was on no medication and had no known allergies. He had no travel history of note, was a non-smoker and drank 14 units of alcohol per week.

On examination, he was laid flat on the trolley and appeared flushed. His temperature was 36.7°C, heart rate was 110 beats per minute, blood pressure 82/40 mmHg, respiratory rate 28 breaths per minute and oxygen saturations 100% on non-rebreather mask. The chest was clear on auscultation and heart sounds were normal. His JVP was not visible. There was some mild right upper quadrant tenderness on palpation of the abdomen, but no guarding or rebound tenderness.

The investigations prior to the biopsy were as follows:

Haemoglobin	160 g/L (130-180)
White cell count	$8.0 \times 10^9/l$
Neutrophil count	$4.0 \times 10^9/l$
Lymphocyte count	$3.0 \times 10^9/l$
Eosinophil count	$0.8 \times 10^9/l$
Platelets	$350 \times 10^9/l$

Sodium	140 mmol/L
Potassium	4.1 mmol/L
Urea	6.5 mmol/L
Creatinine	75 mol/L
Alkaline phosphatase	101 IU/L
Alanine aminotransferase	82 IU/L

Gamma-glutyl transferase	59 IU/L
Bilirubin	18 mol/L
Albumin	36 g/L

Prothrombin time	12 s (10-14)
Activated partial thromboplastin time	38 s (30-45)

Ultrasound abdomen: Hypoechogenic lesion in the right lobe of the liver

What is the most appropriate initial treatment?

<input type="checkbox"/>	Intravenous dobutamine
<input type="checkbox"/>	Intramuscular adrenaline
<input type="checkbox"/>	Intravenous antibiotics
<input type="checkbox"/>	O-negative blood transfusion
<input type="checkbox"/>	Emergency laparotomy

□ Question 142 of 155

An 80-year-old gentleman presented with a 4 month history of feeling generally unwell, being more breathless and tired than usual, feeling feverish and having a dry cough. He had already been treated by the General Practitioner with 2 courses of antibiotics in the community with only temporary improvement. His past medical history includes previous myocardial infarction, permanent pacemaker (PPM) with box-change 8 months ago, hypertension, diabetes, anaemia and chronic kidney disease (stage 2). He is a lifelong smoker.

On examination his heart sounds were normal with no murmurs, he had scattered crackles and his abdomen was soft and non-tender. There was mild leg oedema and a faint purpuric rash on his shins. His vital signs revealed heart rate = 80 beats per minute, blood pressure = 130/70 mmHg, T=37.8oC, SaO₂ = 96% on air and respiratory rate = 20 breaths per minute. His chest X-ray did not show any consolidation and his urine was clear.

The following blood tests have been obtained:

Hb	10.5 g/dl
MCV	95 fl
Platelets	160 * 10 ⁹ /l
WBC	13.4 * 10 ⁹ /l

Na ⁺	132 mmol/l
K ⁺	4.9 mmol/l
Urea	12 mmol/l
Creatinine	150 µmol/l
CRP	100 mg/l

Blood cultures grow coagulase negative staphylococci and you notice that during his previous admission in the hospital he also had positive blood cultures for coagulase-negative staphylococci.

What is the best next investigation?

	Repeat blood cultures
	Computed tomography thorax / abdomen / pelvis
	Biopsy of the rash
	Vasculitic screen
	Urgent transoesophageal echocardiogram

Dashboard

Question 143 of 155

□ □

A 23-year-old man attends the emergency department after arriving back in the UK from a one-year trip travelling in South America. He denies any acute medical problems but reports that he is concerned about a dog bite he had received in Brazil about three months previously. The patient had been on a rain-forest expedition when a dog from the village he was staying in became aggressive and bit him on the left hand, leaving a open wound. The local inhabitants of the village had then chased the dog away. The patient had received first aid from his tour guide and been provided with a course of oral antibiotics. The wound had then healed over the following two weeks. It was only when the patient had been speaking with fellow travellers shortly before he returned to the UK did he realise the possible risk for rabies exposure.

The patient was well in himself and denied any neurological or other symptoms. He had no significant past medical history and took no regular medications. He admitted that he had not adequately researched his travel health needs before leaving the UK and so had not had any vaccinations prior to his trip.

Examination of the patient's wound demonstrated fully healed scars consistent with bite marks across the palm and dorsal surface of the wrist. The limb had normal neurological and vascular examination and the patient reported normal function of the hand.

What is the correct statement regarding rabies post-exposure prophylaxis for this patient?

	The patient should receive rabies vaccination but not rabies immunoglobulin as his wound has now healed
	The patient does not require post-exposure prophylaxis as he remains free of symptoms following the incubation period of rabies
	The patient should receive rabies immunoglobulin and full rabies vaccination schedule
	The patient does not require rabies post-exposure prophylaxis as he did not receive his injury in a high-risk region
	The patient should receive rabies immunoglobulin but not rabies vaccination as this is only of benefit if given pre-exposure

□ Question 144 of 155

A 45-year-old man is urgently referred to dermatology clinic by his general practitioner after presenting with erythema migrans on his left calf. The patient was very concerned about the possibility that he had contracted Lyme disease following his recent walking holiday in the Scottish highlands.

The patient reported returning from his holiday 2 weeks ago and first noticed the rash within the last 24 hours. The patient reported that he had undertaken long walks in the countryside wearing shorts but that he had not noticed any ticks becoming attached to his body during his holiday. Aside from the rash on his leg (described below) the patient reported no other symptoms at the present time or during recent weeks. In particular, the patient denied any symptoms involving the central or peripheral nervous systems.

The patient was in generally good physical health and his only past medical history was hypertension treated with ramipril by his GP. The patient had no known allergies to any medications.

Examination of the patient's left leg demonstrated a circular erythematous rash 15 cm in diameter. The rash demonstrated an appearance typical for erythema migrans, featuring a central spot surrounded by a ring of clear skin and an outer ring of erythema. The patient reported that the area covered by the rash had expanded significantly in the 24 hours since he had first noticed it. A detailed examination of the remaining surface of the patient's skin did not identify any other significant rashes. Examination of the peripheral and central nervous system did not demonstrate any signs of focal neurology. Examination of the cardiovascular, respiratory and abdominal systems was unremarkable. There was no evidence of palpable lymphadenopathy.

What is the appropriate management of this patient's erythema migrans?

	Serological testing for pathogenic <i>Borrelia</i> species
	Treat with doxycycline for 14 days
	No further investigation or treatment required due to absence of history of tick bite
	Review patient in two weeks and arrange serological tests if onset of symptoms or signs of Lyme borreliosis
	Review patient in two weeks and treat with doxycycline if onset of symptoms or signs of Lyme borreliosis

Overall score: **0%**

□ Question 146 of 155

A 23-year-old woman presents to the emergency department. She was brought in by ambulance following left-sided weakness and difficulty in finding words. She also complains of a headache and nausea for the last three days. She has no past medical history and does not smoke nor does she drink alcohol. She recently emigrated from Tanzania to the UK.

On examination, she has marked weakness in upper and lower left limbs and is unable to walk without assistance. Her responses to questions are slow and limited.

Blood tests:

Hb	129 g/l

□ Question 146 of 155

A 23-year-old woman presents to the emergency department. She was brought in by ambulance following left-sided weakness and difficulty in finding words. She also complains of a headache and nausea for the last three days. She has no past medical history and does not smoke nor does she drink alcohol. She recently emigrated from Tanzania to the UK.

On examination, she has marked weakness in upper and lower left limbs and is unable to walk without assistance. Her responses to questions are slow and limited.

Blood tests:

Hb	129 g/l
Platelets	$316 \times 10^9/l$
WBC	$8.9 \times 10^9/l$
Na ⁺	141 mmol/l

Question 147 of 155

A 23-year-old woman presents to GUM clinic. She reports that two days ago she had unprotected vaginal intercourse with a casual partner, who has informed her that he is HIV positive. He claimed to be taking treatment and having good viral control. He has given her a copy of his most recent letter from his HIV clinic confirming that he is on antiretroviral treatment and that his viral load has been <50 (undetectable) for the last year with a CD4 count of 745 cells/mm³. You are able to confirm the validity of this letter as the partner attends the same GUM clinic for his HIV care, and you are also able to confirm the investigations.

She has no past medical history and takes microgynon. She is concerned about catching HIV.

She has undergone STI screening today, including HIV serology. Microscopy is negative for any pathogens. A pregnancy test today is negative.

How should she be further managed?

	Advise repeat STI screen in two weeks and repeat HIV test 8-12 weeks
	Offer HIV post-exposure prophylaxis
	Advise repeat HIV test in 8-12 weeks
	Offer rapid antigen test for HIV and if positive then start HIV post-exposure prophylaxis
	Offer to refer to HIV clinic

□ Question 148 of 155

A 31 year-old accountant was referred to the general medical clinic with persistent nasal stuffiness and intermittent epistaxis. He had been seen by the ear, nose and throat team who had commenced him on a course of intranasal steroids without benefit. His past medical history was unremarkable. His travel history included a gap year in South America 10 years previously. He was a non-smoker and drank 23 units of alcohol per week.

On examination, his temperature was 36.2°C, heart rate 68 beats per minute, respiratory rate 16 breaths per minute, blood pressure 126/82 mmHg. There was some superficial ulceration of the nasal mucosa bilaterally. The chest was clear on auscultation and heart sounds were normal.

Investigations:

Haemoglobin	145 g/L
White cell count	$7.0 \times 10^9/l$
Neutrophil count	$4.0 \times 10^9/l$
Lymphocyte count	$3.0 \times 10^9/l$
Eosinophil count	$0.4 \times 10^9/l$
Platelets	$300 \times 10^9/l$

Sodium	144 mmol/L
Potassium	4.1 mmol/L
Urea	6.1 mmol/L
Creatinine	71 mol/L
Alkaline phosphatase	56 IU/L
Alanine aminotransferase	35 IU/L
Gamma-glutyl transferase	21 IU/L

Bilirubin	13 mol/L
Albumin	39 g/L
Fasting plasma glucose	5.3 mmol/L

What is the most likely causative organism?

<input type="radio"/>	<i>Trypanosoma cruzi</i>
<input type="radio"/>	<i>Plasmodium ovale</i>
<input type="radio"/>	<i>Leishmania braziliensis</i>
<input type="radio"/>	<i>Leishmania donovani</i>

□ □

A 33-year-old male with a previous history of asthma and HIV presents for review to HIV clinic. He has been noticing weight gain, marks on his abdomen and his partner has noticed that his face has been looking more heavy-set over the last two months. He was diagnosed as having HIV at the age of 19 following needle sharing and use of heroin. He has had good retroviral control following starting treatment at the age of 20 with tenofovir, emtricitabine, atazanavir and ritonavir. His asthma has been well controlled with only salbutamol until six months ago when due to recurrent exacerbation due to upper respiratory tract infection his treatment was escalated to include regular fluticasone. Repeat blood tests show an undetectable viral load and a CD4 count of 900 cells/microliter. What is the most likely cause of his symptoms?

	Weight gain secondary to tenofovir use
	Weight gain secondary to emtricitabine use
	Weight gain due to reduced exercise tolerance
	Endogenous Cushing's syndrome
	Iatrogenic Cushing's syndrome

□ □

The Medical Emergency Team (MET) is summoned to the Surgical Unit to assist with the management of an acutely unwell patient.

The patient is a 21-year-old male who underwent open surgery for perforated appendicitis 3 days ago. The Surgical Registrar informs you that faecal contamination of the abdomen was noted during the operation and that a peritoneal washout was performed.

24 hours later, the patient began to complain of worsening abdominal pain. He became febrile in the early hours of the morning and blood cultures were taken. Since then, he has become progressively more unwell. He was taken down for an urgent abdominal ultrasound mid-afternoon, but the nurses were so concerned about his condition when he arrived back on the ward that a MET call was put out.

On examination, the patient is responsive to voice. He is febrile at 38.9°C, his pulse is 131bpm and his blood pressure is 72/53mmHg. His peripheries are warm and clammy. Palpation of the abdomen reveals localised tenderness and guarding in the right iliac fossa. The surgical wound appears clean with minimal surrounding erythema.

As you prepare to place a large bore IV cannula the Surgical FY1 passes you some results that have recently been phoned through:

Abdominal ultrasound	Anechoic fluid collection in the right iliac fossa
Blood culture	Gram-positive cocci both bottles - further information to follow

Which of the following organisms is most likely to be isolated from the blood culture?

	Staphylococcus epidermidis
	Escherichia coli
	Streptococcus pyogenes
	Enterococcus faecalis

Question 151 of 155

□ □

A 30-year-old man is repatriated to the UK from China after being savaged by a dog. He had been working in rural China as an engineer with a non-government organisation. Ten days previously he had been attacked by dog in the street and bitten repeatedly on the right arm. The dog was reported as having been acting very aggressively. It had subsequently been caught and euthanised.

The patient had received prompt local medical attention. His wounds had been washed out in theatre and a course of intravenous antibiotics commenced. Due to issues with tissue loss and possible tendon damage he had been repatriated to the UK for plastic surgery.

As part of the above treatment, the patient had received a full dose of rabies immunoglobulin infiltrated into his wounds two days after the assault. Medical records sent with the patient stated that a course of rabies vaccination had also been initiated, with three doses given so far at day 1, day 4 and day 8 after the injury. The vaccination schedule to date is consistent with the 5 dose Essen regime recommended by the WHO. To complete this schedule, two further doses of vaccination should be given at 14 and 28 days after the first dose.

The recorded serial number of the vaccinations given was checked and found to represent a form of nerve tissue vaccination. On review of current UK supplies this was not found to be available, with only cell culture and embryonate egg-based vaccinations (CCEEVs) in stock. It was also confirmed with the patient that he had never received a course of rabies vaccination previously.

What is the correct ongoing management of this patient's rabies post-exposure prophylaxis?

	Complete vaccination schedule with imported nerve tissue vaccine
	Additional dose rabies immunoglobulin and complete vaccination schedule using available CCEEVs
	Additional dose rabies immunoglobulin and restart vaccination schedule using available CCEEV
	Restart vaccination schedule using available CCEEVs
	Complete vaccination schedule using available CCEEVs

A 23-year-old man presents for the second time to HIV clinic. He was found to have positive HIV serology on opportunistic screening in a local GUM clinic and was referred to HIV services. He had originally presented with dysuria and had been diagnosed with non-specific urethritis and treated with doxycycline. Following his diagnosis, he has separated with his partner, as she feared contracting HIV from him. He is anxious with managing his disease and is keen to start treatment. He has no other symptoms, feeling systemically well and no significant past medical history.

During his previous consultation, his diagnosis was discussed with him, and the role of antiretroviral treatment was fully explained.

Blood tests:

Hb	134 g/l
Platelets	$378 \times 10^9/l$
WBC	$7.2 \times 10^9/l$
Na ⁺	141 mmol/l
K ⁺	4.1 mmol/l
Urea	4.6 mmol/l
Creatinine	64 μ mol/l
HIV viral load	223 copies/ml
CD4 count	914 cells/mm ³

What is the most appropriate management plan offer?

	Start antiretroviral therapy and PCP prophylaxis
	Start antiretroviral therapy
	Start treatment when CD4 count becomes <350

	Start treatment when CD4 count becomes <550
	Start treatment once HIV related symptoms develop

□ Question 154 of 155

□ □

A 35-year-old man is reviewed in respiratory clinic with symptoms of a chronic cough with occasional haemoptysis, night sweats and significant unintentional weight loss. The patient is originally from the Russian Federation and on direct questioning through an interpreter discloses that he had spent five years in a Moscow prison for drugs offences. Aside from a period of alcohol abuse in his early twenties, the patient denies any other medical history and takes no medications. He currently is living in shared accommodation and works on a building site, although he is struggling to continue to work due to his current illness.

General inspection showed the patient to be cachexic with tobacco stained fingernails. Auscultation of the chest revealed some reduced air entry in the upper zones bilaterally. There was palpable lymphadenopathy in the anterior cervical chain.

Please see results of investigations below.

Chest x-ray: patchy shadowing in both upper lobes with evidence of cavity formation on the right side; no pneumothorax; normal mediastinal shadow.

Sputum microscopy: acid fast bacilli

Phenotypic indirect drug susceptibility testing: rifampicin (resistant); ofloxacin (sensitive); moxifloxacin (sensitive); isoniazid (resistant); amikacin (sensitive); capreomycin (sensitive).

What is the most appropriate treatment regime for this patient?

	Combination therapy with 5 drugs for 24-36 months
	Combination therapy with 5 drugs for 18-24 months
	Combination therapy with 4 drugs for 24-36 months
	Combination therapy with 4 drugs for 12 months
	Combination therapy with 4 drugs for 18-24 months

□ Question 154 of 155

□ □

A 35-year-old man is reviewed in respiratory clinic with symptoms of a chronic cough with occasional haemoptysis, night sweats and significant unintentional weight loss. The patient is originally from the Russian Federation and on direct questioning through an interpreter discloses that he had spent five years in a Moscow prison for drugs offences. Aside from a period of alcohol abuse in his early twenties, the patient denies any other medical history and takes no medications. He currently is living in shared accommodation and works on a building site, although he is struggling to continue to work due to his current illness.

General inspection showed the patient to be cachexic with tobacco stained fingernails. Auscultation of the chest revealed some reduced air entry in the upper zones bilaterally. There was palpable lymphadenopathy in the anterior cervical chain.

Please see results of investigations below.

Chest x-ray: patchy shadowing in both upper lobes with evidence of cavity formation on the right side; no pneumothorax; normal mediastinal shadow.

Question 155 of 155

□ □

You are called to see a 50-year-old Indian gentleman who has presented to the Emergency Department (ED) from Heathrow airport. He gives a 3 week history of a brown productive cough associated with fevers and drenching night sweats. He denies any weight loss or haemoptysis, however his wife is concerned that his sputum has been very brown/red in colour since his illness started. On further questioning you find that the patient is a resident of a rural community in north east India and is visiting family who live in London. He is a non-smoker and had been in very good health apart from a bout of diarrhoea several weeks ago.

On examination of the patient he appears relatively well, his heart rate is 95 beats per minute and respiratory rate is 20 breaths per minute. You note that he has a productive cough, producing dark brown sputum which you send for routine microscopy sensitivity and culture (MC&S) and acid fast bacilli (AFB) and tuberculosis PCR. On auscultation of his chest you hear coarse crepitations at the right base with some bronchial breathing. The remainder of his physical examination is unremarkable.

You perform a number of investigations described below

Hb	110 g/l	Na ⁺	138 mmol/l
Platelets	500 * 10 ⁹ /l	K ⁺	4.5 mmol/l
WBC	16.0 * 10 ⁹ /l	Urea	6.0 mmol/l
Neuts	10.0 * 10 ⁹ /l	Creatinine	99 µmol/l
Lymphs	2.0 * 10 ⁹ /l	CRP	55 mg/l
Eosin	2.0 * 10 ⁹ /l		
Sputum MC&S	Negative		
Sputum AFB	Negative		
Chest X-Ray	Right lower zone consolidation		

What is the likely diagnosis?

Tuberculosis

	Streptococcal pneumonia
	Paragonimiasis
	Malignancy
	Pulmonary Haemorrhage

Dashboard

□ Question 1 of 280

□ □

A 56-year-old businessman is admitted to the Emergency Department after suffering a seizure. His wife reports that he has been acting 'strange' for the past few days. She has noticed in particular that he has been 'slow' complaining of feeling tired all the time and also having difficulty finding the right words.

One hour after the seizure had terminated the patient remained confused and appeared to have an ataxic gait after getting up from his bed. During the history he repeatedly said the word 'headache'.

On examination his pulse was 84/min, blood pressure 108/74 mmHg, blood sugar 5.2 mmol/l and temperature 37.9°C.

A **MRI** was requested:

□ Question 4 of 280

A 32 year old presents with a 6 month history of progressive lower limb weakness and suprapubic tenderness. On examination, cranial nerves and upper limbs were unremarkable. You note 1/5 power in both lower limbs, hyper-reflexic patella and ankle reflexes, bilateral clonus and upgoing plantar reflexes. Abdominal examination also revealed a suprapubic mass. After a urethral catheter was inserted, you note a residual volume of 1.8l. She is known to be HIV positive, diagnosed 8 years ago. Blood tests from an outpatient appointment revealed:

CMV IgG	positive
EBV IgG	positive
HTLV antibody	positive
Hepatitis B	negative
Hepatitis C	negative

An MRI spine is awaited. What is the likely diagnosis?

	Tropical spastic paraparesis
	Spinal toxoplasmosis
	CMV transverse myelitis
	EBV transverse myelitis
	Tabes dorsalis

□ Question 5 of 280

A 24 year old man presents to the accident and emergency department with his girlfriend after collapsing in a nightclub at 0400hrs. It is now 0600hrs On examination he is V on the AVPU scale with dry mucous membranes, he has flushed skin and feels very warm to the touch. There is mildly increased muscle tone, myoclonic jerks and hyperreflexia globally but worse in the lower limbs. Pupils are dilated but respond to light equally and bilaterally. He is disorientated and agitated during the examination, thrashing about in the bed and occasionally lashing out at people

Heart rate 126/min, blood pressure 90/60 mmHg, respiratory rate 18/min, temperature = 40.3°C, sats 97% on 10l of oxygen.

Na ⁺	136 mmol/l
K ⁺	3.9 mmol/l
Urea	2.3 mmol/l
Creatinine	77 µmol/l
Glucose	4.6 mmol/l
Creatinine kinase	12,000 U/l

Bilirubin	25 µmol/l
ALP	185 u/l
ALT	125 u/l
γGT	144 u/l
Albumin	40 g/l

CT Head: No abnormality detected.

Lumbar puncture reveals:

Opening pressure	15 cmCSF
Appearance	Clear
Glucose	3.5 mmol/l
Protein	0.3 g/l
White cells	4 / mm ³

He has a past medical history of Schizoaffective disorder. His girlfriend shows you his regular medications, the prescription has been unchanged for 1 year. Olanzapine 15mg and Sertraline 150mg. His girlfriend tells you that he took an unknown white powder whilst in the club

What is the most appropriate treatment plan?

<input type="radio"/>	IV Ceftriaxone
<input type="radio"/>	Stop Olanzapine and give dantrolene
<input type="radio"/>	Stop sertraline and give IV lorazepam and consider cyproheptadine
<input type="radio"/>	Give IV naloxone
<input type="radio"/>	Stop olanzapine and sertraline and supportive therapy

□ Question 7 of 280

□ □

A 50-year-old woman is admitted to the Emergency Department. She has a long history of drug and alcohol abuse and is well known to staff. From her records you can see that she is known to have chronic hepatitis C. A HIV test 6 months ago was negative. She is brought in after having a seizure whilst in police custody. The paramedics describe a generalised tonic-clonic seizure which terminated after 10mg of rectal diazepam was administered.

On admission she is drowsy and demands morphine for her headache. Her pulse is 84/min, blood pressure 116/80 mmHg and temperature 37.2°C. A full neurological examination is not possible as she is drowsy and combative.

A CT scan is arranged:

□ Question 8 of 280

A 44 year-old man presents to the neurology clinic. He complains of weakness in the right hand, which causes difficulty with tasks such as writing and dressing, and has also noted 'twitching' in his right forearm and hand. He cannot recall exactly when the symptoms first began but feels that they have certainly been present for at least six months, and that they have got worse.

He is otherwise fit and well. His only past medical history is well-controlled asthma. There is no family history of neurological disease.

Cranial nerve examination is normal. On examination of the right hand, there is weakness of extension of the the middle and ring fingers (2/5 on the MRC scale), but no discernible muscle wasting. Fasciculations are visible in the dorsal aspect of the forearm. On examination of the left hand, there is also some subtle weakness of extension of the ring finger (4/5 on the MRC scale). There is no weakness of wrist extension on either side and power in all other muscle groups is normal. For both hands, all the fingers extend when the wrist is passively moved into palmar flexion. All reflexes are normal and there are no sensory signs.

What is the most likely diagnosis?

<input type="checkbox"/>	Multifocal motor neuropathy
<input type="checkbox"/>	Chronic inflammatory demyelinating polyneuropathy
<input type="checkbox"/>	Motor neuron disease (amyotrophic lateral sclerosis)
<input type="checkbox"/>	Inclusion body myositis
<input type="checkbox"/>	Ruptured tendon of extensor digitorum

Question 9 of 280

□ □

A 35 year old lady was referred to the neurology clinic for investigation of facial weakness. Over the past 2 months she noticed that her eyelids had tended to drop towards the end of the day, and she had occasional diplopia. She also felt that the corners of her mouth drooped a bit, and she reported some difficulty smiling. There was no limb weakness, and she had not had any difficulty swallowing.

On examination there was a bilateral facial droop, and bilateral partial ptosis. She was sitting with her head tilted up to compensate for this. She had almost complete ptosis after trying to keep her eyes in elevation for more than 15 seconds. Eye movements were otherwise normal. Palatal movement was equal on both sides, and there were no abnormalities in tongue movements. Tone, power, reflexes and sensation were normal in the upper and lower limbs.

What is the most appropriate initial management?

	Mycophenolate mofetil
	Thymectomy
	Prednisolone
	Intravenous immunoglobulin
	Pyridostigmine

Dashboard

Overall score: 0%

Question 10 of 280

□ □

A 35 year old mechanic attends the emergency department following an injury at work. He has suffered a serious laceration to the upper arm. While suturing, the doctor notices multiple cuts and burns on both arms.

On examination there is marked wasting of brachioradialis and the small muscles in both hands, with mild hyporeflexia of the biceps and brachioradialis tendons. He is weak in both arms, distally more so. His lower limb and cranial nerve examination is unremarkable. On testing upper limb sensation, vibration and proprioception are intact but there appears to be reduced pain and temperature sensation over the C3/C4/C5 dermatomes. What is the most useful investigation?

	Lumbar puncture
	Nerve conduction studies
	MRI Brain
	Electromyography
	MRI cervico-thoracic spine

□ Question 12 of 280

A 33-year-old man who has recently emigrated from Zimbabwe is admitted after being found confused at home. His partner reports that he has been acting strangely for a number of weeks and complaining of altered taste and dizziness. She reports that she is HIV positive but her partner refuses to be tested as he does not believe in 'medical lies'.

On admission he is afebrile with a blood pressure of 114/82mmHg and pulse 78/min.

Rapid HIV testing confirms that he has the infection. His CD4 count is 11 cells/ μ l.

An MRI (T1 C+) shows the following:

Other than starting highly active antiretroviral treatment, what is the most appropriate treatment?

	Amphotericin B
	Surgical resection
	Steroids + methotrexate + whole brain irradiation
	Rifampicin + isoniazid + pyrazinamide + ethambutol + steroids
	Sulfadiazine + pyrimethamine

Dashboard

Question 13 of 280

□ □

A 32-year-old male presents with his 4th episode of worst ever headache in one week. He describes the headache to always be of sudden onset on the left side of his head, of 10 out of 10 severity and that he finds bright lights extremely distressing during these periods. The episodes last for around 30 minutes, typically after dinner. He also describes redness and swelling of his left eye and a blocked left nostril during the headaches, associated with tearing of his left eye.

He has no past medical history and family history of migraines. He denies illicit drug use, is a non-smoker and drinks two glasses of wine with dinner every night. Over the past 7 days, he has been self-medicating with paracetamol and ibuprofen. On examination, you notice no focal neurology, no meningism and fundoscopy is unremarkable.

What is the most likely diagnosis?

	Subarachnoid haemorrhage
	First presentations of migraine
	SUNCT (short lasting unilateral neuralgiform headache with conjunctival injection or tearing)
	Medication overuse headache
	Cluster headaches

□ Question 14 of 280

A 19 year old male presents to outpatient clinic with a 3 month history of worsening speech slurring. He finds it extremely embarrassing and is made fun of by his friends in college, who thinks he is turning up to school drunk. He is also finding that he is having difficulty with excessive drooling. Over the past 6 weeks, he has also noted increasing weakness in lifting his right arm. He has no other past medical history, is a non-smoker and drinks alcohol only socially.

On examination, his cranial nerves demonstrate weakness in raising his eyebrows, puffing his cheeks and in pursing his lips. He displays significant scapula winging bilaterally with mild wasting of his right deltoid muscle. Musculature of his left arm is normal. Power of his right shoulder abduction and adduction is 3/5, with 5/5 in all other movements. Reflexes are all present with normal sensory examination.

His blood tests are as follows:

Hb	14.4 g/dl	388 * 10 ⁹ /l
Platelets		
WBC	5.8 * 10 ⁹ /l	

Na ⁺	139 mmol/l
K ⁺	4.7 mmol/l
Urea	4.6 mmol/l
Creatinine	55 µmol/l
CRP	2mg/l
Creatine kinase	150 IU/l (50-335)
TSH	2.3 mu/l
Free T4 nmol/l	
HIV	negative

What is the diagnosis?

	Myoclonic epilepsy with ragged red fibres (MERRF)
	Myotonic dystrophy type 1
	Polymyositis
	Limb girdle muscular dystrophy
	Facioscapulohumeral dystrophy

Dashboard

□ □

A 17 year old girl is brought to the Emergency Department following a prolonged seizure lasting seven minutes. She is known to suffer from epilepsy and has been stable on lamotrigine for eight years, having on average only one generalised tonic clonic seizure every eight months. Her mother describes an increase in her seizure frequency over the last four weeks; she has had three generalised tonic-clonic seizures during this period, each lasting around three minutes. There have been no changes to stress levels, sleep pattern or diet. She confirms she has however started a new medication for dysmenorrhoea. Which is the most likely to explain this increase in frequency?

	Medroxyprogesterone (Depo-Provera)
	Mefenamic acid
	Ibuprofen
	Aspirin
	Naproxen

Question 16 of 280

□ □

A 32 year-old man presents to the neurology clinic with burning pains in both feet, which has progressed over the last year.

His past medical history includes hepatitis C, and last year he was commenced on treatment with pegylated interferon and ribavirin.

On examination, power is normal throughout. Reflexes are present normally in the arms but only with reinforcement in the knees, and absent in the ankles. Sensation to pin-prick, joint position, and vibration is absent up to the knees.

Nerve conduction studies show reduction in the amplitude of lower limb sensory action potentials, in a length-dependent fashion. Conduction velocities are relatively preserved. Motor studies are normal.

What is the most likely cause of this mans pain?

	Diabetic small-fibre neuropathy
	Fabrys disease
	Drug-induced peripheral neuropathy
	Cryoglobulinaemic peripheral neuropathy
	Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP)

Dashboard

Question 17 of 280

□ □

A 65-year-old lady with a history of diabetes and newly diagnosed atrial fibrillation (AF) was admitted to hospital with a moderate-large sized embolic stroke. Her blood pressure on admission was 165/90 mmHg with a heart rate of 95 beats per minute.

An MRI brain was performed 24 hours after admission which showed a moderate to large area of infarction involving the anterior 2/3 of the left middle cerebral artery territory without haemorrhagic transformation.

With regards to management of her AF and stroke prevention, the most appropriate decision would be to commence which of the following?

	An adjusted dose intravenous heparin infusion
	Therapeutic dose low molecular weight heparin (LMWH) and transition to oral anticoagulation in 10-14 days
	Aspirin and wait 10-14 days before commencing formal anticoagulation
	Warfarin with LMWH bridging therapy
	OR calculate the CHADS-vasc score and make a decision

Question 18 of 280

□ □

You are called to a general medical ward during the night to review 48 year female who has become acutely agitated and confused. She came into hospital two days ago with a suspected urinary tract infection and has been making uneventful progress. She has a past history of traumatic spinal injury at level C5 three years ago with resulting spastic quadraparesis. On your arrival her blood pressure is 220/105 mmHg, heart rate is 55/min, and she is flushed and diaphoretic.

Of the following, what additional feature might you expect to find?

	Palpable bladder
	Ejection systolic murmur in the pulmonary area
	Flushing of the skin in the trunk and legs
	Relative afferent pupillary defect
	Complete heart block

Dashboard

Question 20 of 280

A 73-year-old patient is brought in by ambulance to the emergency department. He has had a sudden onset of right-sided weakness and dysphasia which started five hours ago. He undergoes a CT scan and an ischaemic stroke is confirmed with no evidence of acute bleeding.

Due to the delay in presentation to hospital, he is not thought to be suitable for thrombolysis.

He is started on aspirin and admitted to the stroke ward. He has significantly reduced mobility due to his weakness. He is considered to be at risk of haemorrhagic transformation. How should his risk of venous thromboembolism be managed?

<input type="checkbox"/>	Low molecular weight heparin
<input type="checkbox"/>	Unfractionated heparin
<input type="checkbox"/>	Anti-embolic stockings
<input type="checkbox"/>	Intermittent pneumatic compression
<input type="checkbox"/>	Warfarin

□ Question 21 of 280

□ □

A 45 year old woman presents to the Accident and Emergency department after a road traffic accident where she sustains multiple injuries including an open fracture of her left tibia and fibula. The following day she has an open reduction and internal fixation of the left tibia and fibula and remains in hospital for physiotherapy. She is quite immobile during this period and then develops subsequent painful swelling and erythema of the left calf. Subsequent ultrasonography confirms a left sided above knee Deep Vein Thrombosis.

Before treatment starts, she develops sudden onset weakness in her right leg and right arm, dysarthric speech and a reduction in conscious level. Subsequent CT scanning confirms the presence of a left sided infarct in the middle cerebral artery territory. Doppler investigation of the carotids show 20% stenosis on the left side and 10% on the right side. 24hr tape shows average heart rate 52bpm with 1.5s pauses maximum, sinus bradycardia

Which following feature from further investigation would best explain this womans presentation?

	Anti phospholipid antibody positive
	Protein C deficiency
	Patent foramen ovale (PFO)
	Hypercholesterolaemia
	Dilated cardiomyopathy on ECHO

Dashboard

Question 24 of 280

A 24-year-old female is reporting difficulty in walking in an inpatient rehabilitation unit during recovery from spinal surgery. Six weeks previously, she underwent emergency spinal haematoma evacuation surgery under the neurosurgeons from T2 to T4 after sustaining a fall playing netball. She was previously fit and well, with no past medical history, giving birth to a healthy baby boy 18 months ago.

On examination, the patient has normal tone in her upper and lower limbs. Examination of her power while lying on her bed demonstrates 5/5 on the MRC power scale with normal sensation to cotton wool, pin prick and proprioception. Reflexes were present (2+) in her biceps, triceps, supinator, patella and ankles, both plantars were downgoing. On walking, the patient's gait is markedly abnormal, with both feet sliding along the floor for 80 metres of walking without lifting of her feet between steps. Cognition is intact. What is the optimal management?

	Repeat MRI head
	Repeat MRI whole spine
	Nerve conduction studies and electromyography
	Lumbar puncture
	Education and reassurance

Dashboard

Question 25 of 280

□ □

A 76-year-old right-handed female presents with sudden onset flaccid right upper and lower paralysis with complete dysphasia. Her daughter reports her to have been well two hours ago.

On examination, the patients score 0/5 on her right upper and lower limb, at least 4/5 on both left limbs (examination was difficult due to her dysphasia), with a loud carotid bruit. She is also now in atrial fibrillation, a new diagnosis for her. She is well known to the stroke team: 6 weeks ago, she was admitted with a right middle cerebral artery ischaemic stroke, leaving her with minimal residual weakness on her discharge.

During her admission, she was found to have 85% carotid stenosis in her right internal carotid artery and 75% in her left internal carotid artery, for which she declined surgery. Her other past medical history includes hypertension, type 2 diabetes mellitus and dyslipidaemia. She does not take any anticoagulants. A CT head demonstrates a hypodensity in the left middle cerebral artery area distribution, consistent with an acute ischaemic stroke with no areas of haemorrhagic transformation.

What is the most appropriate next course of action?

	Intravenous alteplase
	Clopidogrel 75mg
	Aspirin 300mg
	Treatment dose low molecular weight heparin
	Warfarin

Question 25 of 280

□ □

A 76-year-old right-handed female presents with sudden onset flaccid right upper and lower paralysis with complete dysphasia. Her daughter reports her to have been well two hours ago.

On examination, the patients score 0/5 on her right upper and lower limb, at least 4/5 on both left limbs (examination was difficult due to her dysphasia), with a loud carotid bruit. She is also now in atrial fibrillation, a new diagnosis for her. She is well known to the stroke team: 6 weeks ago, she was admitted with a right middle cerebral artery ischaemic stroke, leaving her with minimal residual weakness on her discharge.

During her admission, she was found to have 85% carotid stenosis in her right internal carotid artery and 75% in her left internal carotid artery, for which she declined surgery. Her other past medical history includes hypertension, type 2 diabetes mellitus and dyslipidaemia. She does not take any anticoagulants. A CT head demonstrates a hypodensity in the left middle cerebral artery area distribution, consistent with an acute ischaemic stroke with no areas of haemorrhagic transformation.

Question 26 of 280

□ □

A 28 year-old woman presents with a two month history of double vision, which is worse at the end of each day. On examination, there is bilateral ptosis which is fatiguable. There is a complex ophthalmoplegia which does not conform to the pattern of one or more cranial nerves. Examination of the limbs is unremarkable.

Which of the following would be most suggestive of a diagnosis of myasthenia gravis?

	Weakness confined to extraocular muscles
	A decremental response to repetitive nerve stimulation
	An incremental response to repetitive nerve stimulation
	Thymic enlargement seen on chest imaging
	Internuclear ophthalmoplegia

Question 27 of 280

A 80 year old woman is referred to neurology clinic after experiencing increasing diplopia, typically worsening during the course of the day. The patient reported no speech or swallowing problems and no limb weakness.

Past medical history included chronic obstructive pulmonary disease and ischaemic heart disease. The patient was able to mobilise around her flat with a frame but was required to use a wheelchair outside the home due to exertional breathlessness. Regular medications were inhaled salbutamol and tiotropium, aspirin, simvastatin, bisoprolol and ramipril. The patient lived with her husband and had once daily carers to assist with activities of daily living.

Examination in clinic was significant for the development of ptosis on prolonged upwards gaze. There was no significant weakness of facial muscles, palate or tongue. There was no evidence of fatiguable weakness in the arms or legs.

A summary of the patients investigations is given below.

Serum acetylcholine receptor antibodies	negative
Serum muscle specific tyrosine kinase	positive

Neurophysiology: no evidence of repetitive nerve stimulation

CT thorax: retro-sternal soft-tissue density mass equal in attenuation to muscle; mass demonstrates heterogeneous enhancement following contrast injection

What is the appropriate management of the retro-sternal mass?

<input type="checkbox"/>	Proceed to thymectomy
<input type="checkbox"/>	Proceed to thymectomy if patient does not respond to first line treatment
<input type="checkbox"/>	Surgical biopsy
<input type="checkbox"/>	No action required
<input type="checkbox"/>	Trans-bronchial biopsy

Question 28 of 280

A 32 year old man presents to your haematology clinic with a 4 year history of fatigue, weight loss and a feeling of fullness in the stomach. He has been off sick from work for the past 3 months and has recently been divorced. He also complains of low mood and has attempted suicide in the past. He has a family history of NHL. He has been investigated in the past with CT scans, blood films and lymph node biopsies on several occasions with the most recent set of investigations occurring 6 months ago.

Despite your reassurances that he does not have a lymphoma, he is still convinced that he does and that he is dying. You suggest a referral to a psychiatrist and he becomes very angry. What is the most likely underlying diagnosis?

	Atypical depression
	Specific phobia
	Hypochondriasis
	Conversion disorder
	Somatoform disorder

Question 29 of 280

A 14-year-old boy presents his third generalised seizure over the past 72 hours, despite recently being started on sodium valproate by a neurologist for recurrent seizures 6 weeks ago, with worsening vision at night and hearing loss bilaterally. The patient has a number of myoclonic jerks as you arrive. On examination, his heart sounds are unremarkable but you notice a tachycardia at 140 and regular. The ECG is shown below:

© Image used on license from Dr Smith, University of Minnesota

The patient is uncooperative to further neurological examination but you notice sluggishly reactive pupils of equal size. His mother reports that he has been educated in a special needs school for the past 5 years but had been attending the local primary school until aged 9, when he dropped further behind than his peers. Which investigation produces the underlying diagnosis?

	MRI
	Lumbar puncture
	Electroencephalogram (EEG)
	Cardiac electrophysiology studies
	Muscle biopsy

Question 30 of 280

□ □

A 75-year-old man is being reviewed after transient expressive dysphasia and clumsiness in the right hand. His symptoms completely resolved after 20 minutes.

He does not have a background diagnosis of ischaemic heart disease or diabetes but is an ex-smoker with a 50 pack year history. His blood pressure was 160/70 mmHg and he was in sinus rhythm. He had no detectable neurological signs on examination.

His MRI brain scan showed a very small area of restricted diffusion in the left frontotemporal region consistent with ischaemia.

He has a total fasting cholesterol of 4 mmol/L (normal) with an LDL level of 2.5 mmol/L (normal). With regards to cholesterol, in addition to dietary advice and exercise what else may benefit this patient?

	Commence on a fibrate
	Commence a statin
	Commence a fibrate and a statin
	Commence fish oil tablets
	Assess for diabetes and only if present commence a statin

Dashboard

Question 31 of 280

□ □

A 30 year-old HIV positive South African woman presents to the emergency department with a 12 day history of fever and headache. On examination she is found to have a 6th nerve palsy, papilloedema and erythematous skin papules across her torso. She is not on any medication.

Investigations:

CD4 count	90 cells / mm ³
-----------	----------------------------

CT head: Normal

What is the most appropriate immediate management?

	Intravenous ceftriaxone
	Anti-retroviral therapy
	Rifampicin, isoniazid, pyrazinamide & ethambutol
	Intravenous albendazole & hydrocortisone
	Intravenous amphotericin B & flucytosine
